1 QUESTIONS

QUESTION 1.1. What is the desired formatting for the title page and (yet to exist) introduction?

QUESTION 1.2. How to cite the stacks project correctly?

2 Introduction

(TBD)

Definition 2.1. Throughout, we say a *variety* is an integral separated scheme of finite type over a field k , a *curve* is a dimension one variety, and a *surface* is a dimension two variety.

3 A Brief Review of Toric Geometry

Definition 3.1. A *toric variety* X is a normal variety over k with a dense open embedding of the torus $\mathbb{T}^n = \mathbb{G}_{m,k}^n \hookrightarrow X$ with $n = \dim X$ such that the natural action of the torus on itself as a group scheme extends to an action $\mathbb{T}^n \times X \rightarrow X$.

Remark. Any toric variety is rational since $\mathbb{P}_k^n \xrightarrow{\sim} X$ may be defined by the inclusion of the torus $\mathbb{G}_{m,k}^n \hookrightarrow X$ which is a dense open immersion and thus gives an isomorphism between dense open subsets of \mathbb{P}_k^n and X .

3.1 The Toric Variety Associated to a Fan

Our notation here follows Cox's text and lectures [CLS11, Cox05] for the discussion of the objects of combinatorial geometry and their corresponding toric data.

Definition 3.2. Here we fix a lattice N and let M denote its dual lattice with the canonical pairing $\langle, \rangle : M \times N \rightarrow \mathbb{Z}$. Then $N_{\mathbb{R}} = N \otimes_{\mathbb{Z}} \mathbb{R}$ and $M_{\mathbb{R}} = M \otimes_{\mathbb{Z}} \mathbb{R} = (N_{\mathbb{R}})^*$. We define the following convex geometric objects,

- (a). a *cone* $\sigma \subset N_{\mathbb{R}}$ is a subset closed under addition and positive scaling by \mathbb{R}^+
- (b). a *convex polyhedral cone* is a cone $\sigma \subset N_{\mathbb{R}}$ which is generated by a finite set $\sigma = \text{Cone}(\{v_1, \dots, v_n\})$ for $v_1, \dots, v_n \in N_{\mathbb{R}}$
- (c). a *rational polyhedral cone* is a cone $\sigma \subset N_{\mathbb{R}}$ such that $\sigma = \text{Cone}(\{S\})$ for a finite set $S \subset N$ i.e. σ is generated by a finite number of integral lattice points
- (d). $\dim \sigma = \dim \text{span}\{\sigma\}$

Definition 3.3. Given a cone $\sigma \subset N_{\mathbb{R}}$ we define the *dual cone*,

$$\sigma^\vee = \{m \in M \mid \forall n \in \sigma : \langle m, n \rangle \geq 0\}$$

Definition 3.4. Given a cone $\sigma \subset N_{\mathbb{R}}$ we define the *associated monoid*,

$$S_\sigma = \sigma^\vee \cap M$$

Lemma 3.5 (Gordon). If $\sigma \subset N_{\mathbb{R}}$ is a rational polyhedral cone then $S_\sigma = \sigma^\vee \cap M$ is a finitely generated monoid.

Definition 3.6. A cone $\sigma \subset N_{\mathbb{R}}$ is called *strongly convex* if it satisfies one of the following equivalent conditions,

- (a). $\sigma \cap (-\sigma) = \{0\}$
- (b). $\dim \sigma^\vee = n$
- (c). $\{0\}$ is a face of σ
- (d). σ contains no positive-dimensional vector spaces

Definition 3.7. Let k be a field and S a monoid. Then the monoid algebra $k[S]$ is generated by monomials of the form χ^m for $m \in S$ satisfying $\chi^{m_1+m_2} = \chi^{m_1} \cdot \chi^{m_2}$.

Remark. The functor $k[-] : \mathbf{CMon} \rightarrow \mathbf{Alg}_k$ is left-adjoint to the forgetful functor via,

$$\mathrm{Hom}_k(k[S], A) = \mathrm{Hom}_{\mathbf{CMon}}((S, +), (A, \times))$$

Thus $k[S]$ represents the functor $\mathbf{Alg}_k^{\mathrm{op}} \rightarrow \mathbf{Set}$ sending $S \mapsto \mathrm{Hom}_{\mathbf{CMon}}((S, +), (A, \times))$.

Definition 3.8. Let $\sigma \subset N_{\mathbb{R}}$ be a strongly convex rational polyhedral cone. Then the associated affine toric variety is,

$$U_{\sigma} = \mathrm{Spec}(k[S_{\sigma}]) = \mathrm{Spec}(k[\sigma^{\vee} \cap M])$$

with torus $\mathrm{Spec}(k[M]) \rightarrow \mathrm{Spec}(k[S_{\sigma}])$ via $S_{\sigma} \subset M$ and thus $k[S_{\sigma}] \hookrightarrow k[M]$ is a localization map since $\dim \sigma^{\vee} = n$. Furthermore, choosing $M \cong \mathbb{Z}^n$,

$$\mathrm{Spec}(k[M]) = \mathrm{Spec}(k[\mathbb{Z}^n]) = \mathbb{G}_{m,k}^n$$

Theorem 3.9. Let U be an affine toric variety. Then $U = \mathrm{Spec}(k[S_{\sigma}])$ for some strongly convex rational polyhedral cone.

Proof. See [CLS11, Thm. 1.3.5]. □

Remark. The equivalence between affine toric varieties and convex polyhedral cones holds since we require toric varieties to be normal. Without this assumption, an affine toric variety may be generated by a non-saturated monoid (e.g. [Cox05, Ex. 1.10]).

Remark. If τ is a face of σ then $S_{\tau} \supset S_{\sigma}$ induces $k[S_{\sigma}] \rightarrow k[S_{\tau}]$ and thus a morphism $X_{\tau} \rightarrow \mathbb{T}_{\Sigma}$ which is an open embedding because it at the level of rings it is injective.

Definition 3.10. A *fan* is a collection Σ of strongly convex rational polyhedral cones in $N_{\mathbb{R}}$ such that,

- (a). $\forall \sigma \in \Sigma$ and any face τ of σ then $\tau \in \Sigma$
- (b). $\forall \sigma, \tau \in \Sigma$ the intersection $\sigma \cap \tau$ is a common face of σ and τ and $\sigma \cap \tau \in \Sigma$.

Given a fan Σ we define the sets,

$$\Sigma(k) = \{\sigma \in \Sigma \mid \dim \sigma = k\}$$

Remark. The smallest face of a fan Σ is $\{0\}$ for which $\{0\}^{\vee} = M$ and thus defines the torus,

$$U_{\{0\}} = \mathrm{Spec}(k[M]) \cong \mathrm{Spec}(k[\mathbb{Z}^n]) = \mathbb{G}_{m,k}^n$$

which is the torus.

Remark. If σ and τ intersect in a common face $S_{\sigma \cap \tau} = S_{\sigma} + S_{\tau}$ then the embeddings $U_{\sigma \cap \tau} \rightarrow U_{\sigma}, U_{\tau}$ allow gluing.

Definition 3.11. Given a fan Σ we define the toric variety \mathbb{T}_{Σ} via gluing U_{σ} for each $\sigma \in \Sigma$. This gluing may alternatively be described via the functor,

$$\mathfrak{S}_{\mathbb{T}_{\Sigma} \rightarrow \mathrm{Spec}(k)} : \mathbf{Alg}_k \rightarrow \mathbf{Set}$$

$$A \mapsto \left\{ \bigcup_{\sigma \in \Sigma} S_{\sigma} \rightarrow A \quad \middle| \quad \forall \sigma \in \Sigma : f|_{S_{\sigma}} \rightarrow (A, \times) \text{ is a morphism of monoids} \right\}$$

which is represented by the scheme \mathbb{T}_{Σ} . Then \mathbb{T}_{Σ} is a variety over k .

Finally, we discuss the relationship between the structure of a toric variety defined by a fan and the combinatorial structure of the fan. In particular, the closure of the torus \mathbb{T}^n has interesting structure at infinity which corresponds to the nonzero cones as follows.

Proposition 3.12. For each cone $\sigma \in \Sigma$ we define the locally closed subset of \mathbb{T}_Σ ,

$$O(\sigma) := U_\sigma \setminus \left(\bigcup_{\tau \prec \sigma} U_\tau \right)$$

where $\tau \prec \sigma$ if τ is a proper face of σ . Then $O(\sigma) = \mathbb{T}^n \cdot \gamma_\sigma$ is a torus-orbit with a distinguished point $\gamma_\sigma \in U_\sigma$ defined as follows by the maximal ideal $\mathfrak{m}_\sigma \subset k[S_\sigma]$ generated by χ^m for $m \in S_\sigma = \sigma^\vee \cap M$ such that $\langle m, n \rangle > 0$ for all $n \in \sigma$.

Furthermore, let $V(\sigma) = \overline{O(\sigma)}$ then $V(\sigma)$ is the toric variety corresponding to the lattice N/N_σ where $N_\sigma = \text{Span}(\sigma \cap N)$ with fan $\Sigma_\sigma \subset (N/N_\sigma) \otimes_{\mathbb{Z}} \mathbb{R}$ which has cones,

$$\Sigma_\sigma \leftrightarrow \text{Star}(\sigma) = \{\tau \in \Sigma \mid \tau \supset \sigma\}$$

$$\bar{\tau} = (\tau + (N_\sigma)_\mathbb{R}) / (N_\sigma)_\mathbb{R} \subset N_\mathbb{R} / (N_\sigma)_\mathbb{R} = (N/N_\sigma)_\mathbb{R}$$

where the torus of $V(\sigma)$ is $O(\sigma) = U_{\bar{\sigma}} = \text{Spec}(k[N/N_\sigma]) \cong \mathbb{G}_{m,k}^{n-\dim \sigma}$ whose closed points are naturally isomorphic to $T(N/N_\sigma) = (N/N_\sigma) \otimes_{\mathbb{Z}} k^\times$.

Proof. See [Cox05, Lec. 2]. □

Theorem 3.13 (Cone-Orbit Correspondence). There is a correspondence between cones and orbits,

- (a). $\{\text{cones } \sigma \in \Sigma\} \leftrightarrow \{\mathbb{T}^n \text{ - orbits of } \mathbb{T}_\Sigma\}$ via $\sigma \mapsto O(\sigma)$ is a bijection
- (b). $\dim \sigma + \dim O(\sigma) = n$
- (c). $O(\tau) \subset \overline{O(\sigma)} \iff \sigma \subset \tau$

and an inclusion-reversing correspondence between cones and torus-invariant closed subvarieties,

- (a). $\{\text{cones } \sigma \in \Sigma\} \leftrightarrow \{\mathbb{T}^n \text{- invariant closed subvarieties of } \mathbb{T}_\Sigma\}$ via $\sigma \mapsto V(\sigma)$ is a bijection
- (b). $\dim \sigma + \dim V(\sigma) = n$
- (c). $V(\tau) \subset V(\sigma) \iff \sigma \subset \tau$.

In particular, for each σ there is a partition,

$$V(\sigma) = \bigcup_{\tau \supset \sigma} O(\tau)$$

Proof. See [Cox05, Lec. 2]. □

Remark. We say that $D_\mathbb{T} = \mathbb{T}_\Sigma \setminus \mathbb{T}$ is the toric divisor of \mathbb{T}_Σ which is \mathbb{T} -invariant and,

$$D_\mathbb{T} = \bigcup_{\sigma \neq \{0\}} V(\sigma) = \bigcup_{\sigma \neq \{0\}} O(\sigma)$$

so $D_\mathbb{T}$ is a union of toric varieties.

3.2 Smoothness and Singularities of Toric Varieties

Lemma 3.14. The affine toric variety U_σ of a cone $\sigma \subset N \otimes_{\mathbb{Z}} \mathbb{R}$ is smooth if and only if $\sigma \cap N$ has a minimal generating set which can be extended to a basis of the lattice N .

This observation motivates the following definition:

Definition 3.15. We call a rational polyhedral cone $\sigma \subset N \otimes_{\mathbb{Z}} \mathbb{R}$ *smooth* if it has a minimal integral generating set of $\sigma \cap N$ which is a subset of a basis of the lattice N . Otherwise we say that σ is *singular*.

Example 3.16. The cone $\sigma = \text{Cone}(\{(1,0), (0,1)\})$ is smooth since it is generated by a basis of \mathbb{Z}^2 . However, the cone $\text{Cone}(\{(1,0), (2,3)\})$ is not smooth because these are the minimal integral generators and they do not form a basis of the lattice \mathbb{Z}^2 since $(0,1)$ is not in their \mathbb{Z} -span.

Lemma 3.17. The singular locus of the toric variety \mathbb{T}_Σ associated to a fan Σ in terms of the singular cones,

$$(\mathbb{T}_\Sigma)_{\text{sing}} = \bigcup_{\sigma \in \Sigma \text{ singular}} V(\sigma)$$

and thus conversely the regular locus is,

$$\mathbb{T}_\Sigma \setminus (\mathbb{T}_\Sigma)_{\text{sing}} = \bigcup_{\sigma \in \Sigma \text{ smooth}} U_\sigma$$

In particular, the toric variety \mathbb{T}_Σ is smooth iff Σ is smooth meaning that every cone $\sigma \in \Sigma$ is smooth.

Proof. Notice that, because of the toric action of the orbits $O(\sigma)$ if any point in $O(\sigma)$ is singular then every point will be singular. It is clear that if a cone σ is contained in a cone τ then if σ is singular then so is τ which implies that,

$$(\mathbb{T}_\Sigma)_{\text{sing}} = \bigcup_{\sigma \in \Sigma \text{ singular}} O(\sigma) = \bigcup_{\sigma \in \Sigma \text{ singular}} V(\sigma)$$

since the closures of the orbit $O(\sigma)$ corresponds to taking the union of the orbits corresponding to all cones containing σ . \square

QUESTION 3.18. Okay for non-perfect fields is regular locus and smooth locus the same for toric varieties? I can restrict to perfect fields so it should be fine but just wondering.

Proposition 3.19. The toric variety defined by a fan is normal.

Proof. We sketch this by showing that \mathbb{T}_Σ is regular in codimension one. The essential observation is that any one-dimensional cone $\sigma \subset N \otimes_{\mathbb{Z}} \mathbb{R}$ is smooth. This is because the minimal generator in $\sigma \cap N$ is (a_1, \dots, a_n) which are totally coprime meaning they generate the unit ideal in \mathbb{Z} and thus form a row of some matrix $A \in \text{GL}_n(\mathbb{Z})$ which exactly shows that σ is smooth (we can find a matrix $B \in \text{GL}_n(\mathbb{Z})$ with $B(a_1, \dots, a_n) = e_1$ then let $A = B^{-1}$). Therefore, the singular locus,

$$(\mathbb{T}_\Sigma)_{\text{sing}} = \bigcup_{\sigma \in \Sigma \text{ singular}} V(\sigma) \subset \bigcup_{\sigma \in \Sigma | \dim \sigma > 1} V(\sigma)$$

is a finite union of closed codimension > 1 toric components and thus is closed of codimension at least two. Then let $Z \subset \mathbb{T}_\Sigma$ be an irreducible codimension one closed subscheme with generic point η . If $\eta \in (\mathbb{T}_\Sigma)_{\text{sing}}$ then $Z \subset (\mathbb{T}_\Sigma)_{\text{sing}}$ since it is closed contradicting the fact that the singular locus lies in codimension at least two. \square

We now summarize the smoothness properties of the toric variety \mathbb{T}_Σ associated to a fan.

Theorem 3.20. The toric variety \mathbb{T}_Σ associated to the fan Σ is,

- (a). normal
- (b). Cohen-Macaulay
- (c). smooth exactly when Σ is smooth
- (d). complete exactly when Σ is complete i.e. $|\Sigma| = N_\mathbb{R}$.

Proof. See [Cox05, Lec. 2, Thm. 2.3]. □

3.3 Toric Divisors

Let us briefly review our definitions of divisors to clarify notation. Let \mathcal{K}_X be the sheaf of meromorphic functions on X then the sheaf of Cartier divisors is $\mathfrak{Div}_X = \mathcal{K}_X^\times / \mathcal{O}_X^\times$ and a Cartier divisor is a section $D \in H^0(X, \mathfrak{Div}_X)$. Then the Cartier class group $\text{CaCl}(X)$ is the cokernel of $H^0(X, \mathcal{K}_X^\times) \rightarrow H^0(X, \mathfrak{Div}_X)$ then a basic cohomology calculation gives a natural embedding $\text{CaCl}(X) \hookrightarrow \text{Pic}(X)$ which is an isomorphism when $H^1(X, \mathcal{K}_X^\times) = 0$ (in particular when X is integral). When X satisfies the Weil property,

(W) X is a Noetherian, integral, separated scheme which is regular in codimension one.

we define a prime divisor Z on X to be a codimension one integral closed subscheme and a Weil divisor $D \in \text{Div}(X)$ to be a formal (finite) sum of prime divisors of X . A principal divisor is of the form $(f) \in \text{Div}(X)$ for $f \in K_X^\times$ where,

$$\text{div}(f) = \sum_{Z \text{ prime}} \text{ord}_Z(f) [Z]$$

then $\text{Cl}(X)$ is the group of Weil divisors modulo principal divisors. Furthermore, any Weil divisor class injectively defines a coherent sheaf $\mathcal{O}_X(D)$ with the following property,

$$\Gamma(U, \mathcal{O}_X(D)|_U) = \{f \in K(X) \mid \text{div}(f) + D \geq 0 \text{ on } U \text{ or } f = 0\}$$

There is a canonical embedding $\text{CaCl}(X) \hookrightarrow \text{Cl}(X)$ which is an isomorphism when X is locally factorial. A Weil divisor is a Cartier divisor (i.e. is in the image of $\text{CaCl}(X) \hookrightarrow \text{Cl}(X)$) if and only if $\mathcal{O}_X(D)$ is invertible which is then the corresponding line bundle under $\text{CaCl}(X) \hookrightarrow \text{Pic}(X)$.

Remark. Note that the map $\mathcal{O}_X(D) \otimes_{\mathcal{O}_X} \mathcal{O}_X(E) \rightarrow \mathcal{O}_X(D + E)$ given by $f \otimes g \mapsto fg$ is an isomorphism if one of D or E is Cartier but may, in general, fail to be an isomorphism.

Note that (W) always holds for toric varieties since they are normal varieties. Therefore, in the toric case, we have $\text{Pic}(X) = \text{CaCl}(X) \hookrightarrow \text{Cl}(X)$ which is an isomorphism when X is smooth. However, toric varieties have a special class of divisors, those which are invariant under the torus action which, for Weil divisors, are exactly generated by prime divisors supported on the toric divisor $D_\mathbb{T} = X \setminus \mathbb{T}^n$. Such prime divisors are exactly the codimension one torus-invariant closed subschemes which, by the cone-orbit correspondence, correspond to $V(\rho)$ for rays $\rho \in \Sigma(1)$. We call these prime advisors $D_\rho = V(\rho)$ for each $\rho \in \Sigma(1)$. The fundamental property of divisors on toric varieties is that any divisor is linearly equivalent to a torus-invariant divisor which follows from the following lemma.

Lemma 3.21. Let X satisfy (W) and $U = X \setminus Z$ with $Z \subset X$ be a closed subscheme which is the union of s prime divisors. Then there is an exact sequence,

$$\mathbb{Z}^s \longrightarrow \mathrm{Cl}(X) \longrightarrow \mathrm{Cl}(U) \longrightarrow 0$$

Proof. The closure of any prime divisor $Y \subset U$ in X gives a prime divisor $\overline{Y} \subset X$ so $\mathrm{Cl}(X) \rightarrow \mathrm{Cl}(U)$ is surjective. The kernel is exactly the divisors supported on Z which is generated by the prime divisors decomposing Z giving a map $\mathbb{Z}^s \rightarrow \mathrm{Cl}(X)$. \square

Applying this to a toric variety X with torus $\mathbb{T}^n \hookrightarrow X$ then $\mathrm{Cl}(\mathbb{T}^n) = \mathrm{Cl}(\mathbb{G}_{m,k}^n) = 0$ so we get a surjection $\mathbb{Z}^s \twoheadrightarrow \mathrm{Cl}(X)$. In particular, every Weil divisor class is generated by the torus-invariant prime divisors so every Weil divisor is linearly equivalent to some torus-invariant Weil divisor. Additionally, we can identify $\mathrm{Cl}(X)$ exactly as a quotient of \mathbb{Z}^s as follows.

Proposition 3.22. Let X be the toric variety of the fan $\Sigma \subset N_{\mathbb{R}}$ then there is an exact sequence,

$$0 \longrightarrow M \longrightarrow \mathbb{Z}^{\Sigma(1)} \longrightarrow \mathrm{Cl}(X) \longrightarrow 0$$

where $\mathbb{Z}^{\Sigma(1)}$ is the free group on the divisors D_{ρ} for $\rho \in \Sigma(1)$.

Proof. The codimension one irreducible toric-invariant closed subschemes are exactly the closures of the torus orbits $V(\rho)$ for $\rho \in \Sigma(1)$ and the toric divisor $D_{\mathbb{T}}$ decomposes as,

$$D_{\mathbb{T}} = \bigcup_{\rho \in \Sigma(1)} D_{\rho}$$

so $s = |\Sigma(1)|$ in the previous lemma giving exactness on the right. The kernel of $\mathbb{Z}^s \rightarrow \mathrm{Cl}(X)$ consists of principal Weil divisors $\mathrm{div}(f)$ which are supported on $D_{\mathbb{T}}$ then $f \in K(X) = \mathrm{Frac}(k[M])$ has no poles or zeros on the torus $\mathbb{T} = \mathrm{Spec}(k[M])$ so it must be a unit $f = u\chi^m$ for $u \in k^{\times}$ and $m \in M$. Thus, there kernel is the image of $M \rightarrow \mathbb{Z}^s$ given by $m \mapsto (\mathrm{ord}_{D_{\rho_i}}(\chi^m))$ which is injective by the following calculation. \square

Lemma 3.23. Consider a ray $\rho \in \Sigma(1)$ with minimal generator v_{ρ} in N then,

$$\mathrm{ord}_{D_{\rho}}(\chi^u) = \langle u, v_{\rho} \rangle$$

Proof. Choosing a basis e_i of the lattice N extending $e_1 = v_{\rho}$, we can assume that $U_{\rho} \cong k[x_1, x_2^{\pm 1}, \dots, x_n^{\pm 1}]$ since ρ is a cone where x_i is character of the dual basis e_i^* . Then $m = \langle m, e_1 \rangle e_1^* + \dots + \langle m, e_n \rangle e_n^*$ and therefore,

$$\chi^m = x_1^{\langle m, e_1 \rangle} \dots x_n^{\langle m, e_n \rangle}$$

Now since $D_{\rho} = V(x_1) \subset U_{\rho}$ we see immediately that,

$$\mathrm{ord}_{D_{\rho}}(\chi^m) = \nu_{x_1}(\chi^m) = \langle m, e_1 \rangle = \langle m, v_{\rho} \rangle$$

See [CLS11, Prop. 4.1.1] for further details. \square

Following with our program of assigning geometric objects on toric varieties to combinatorial data in terms of the convex fan, we define the notion of polytopes associated to divisors and support functions which compute the torus-invariant Cartier divisors and thus the Picard group.

Definition 3.24. Let D be a torus-invariant Weil divisor on \mathbb{T}_Σ . Then, we define a rational polytope $P_D \subset M_\mathbb{R}$ as follows. Write,

$$D = \sum_{\rho \in \Sigma(1)} a_\rho D_\rho$$

and define,

$$P_D = \{m \in M_\mathbb{R} \mid \forall \rho \in \Sigma(1) : \langle m, v_\rho \rangle \geq -a_\rho\} = \bigcap_{\rho \in \Sigma(1)} H^+(v_\rho, -a_\rho)$$

Remark. Since P_D is the intersection of rational half-spaces it is clearly a rational polytope. Furthermore, if Σ is complete then v_ρ spans N and thus P_D is compact. However, it is not necessarily an integral polytope. However, this demonstrates that for any divisor $P_{nD} = nP_D$ is an integral polytope for sufficiently large n .

Definition 3.25. A *support function* is a continuous function $\psi : |\Sigma| \rightarrow \mathbb{R}$ such that on each cone $\sigma \in \Sigma$ the restriction $\psi|_\sigma(x) = \langle m_\sigma, x \rangle$ is linear. A global support function is a function of the form $\langle m, - \rangle$ for a global choice of $m \in M$. We define the Picard group of the fan to be the quotient by global support functions $\text{Pic}(\Sigma) = SF(\Sigma)/M$.

Proposition 3.26. On a toric variety \mathbb{T}_Σ , there is a correspondence between torus-invariant Cartier divisors D and support functions ψ_D . Given by,

$$D \mapsto \psi_D \text{ such that } \psi|_\sigma = \langle u(\sigma), - \rangle \text{ where } D|_{U_\sigma} = \text{div}(\chi^{-u(\sigma)})$$

and

$$\psi \mapsto \{(U_\sigma, \chi^{-m_\sigma}) \mid \sigma \in \Sigma\}$$

We may furthermore assign a Weil divisor to ψ via the map $\text{CaCl}(X) \rightarrow \text{Cl}(X)$,

$$\psi \mapsto \sum_{\rho \in \Sigma(1)} \text{ord}_{D_\rho}(\chi^{-m_\rho}) D_\rho = \sum_{\rho \in \Sigma(1)} -\langle m_\rho, v_\rho \rangle D_\rho = \sum_{\rho \in \Sigma(1)} -\psi(v_\rho) D_\rho$$

where we recall that $\Sigma(1)$ corresponds to the set of torus-invariant prime divisors.

Proof. The condition that the Cartier divisor must agree up to a unit is equivalent to the following requirement. Since χ^{-m} does not vanish on the torus, to check that $\chi^{-m(\sigma)}$ and $\chi^{-m(\tau)}$ differ by a unit on $U_\sigma \cap U_\tau$, it suffices to show that $\text{ord}_{D_\rho}(\chi^{-m(\sigma)}) = \text{ord}_{D_\rho}(\chi^{-m(\tau)})$ for each $\rho \subset \sigma \cap \tau$ which corresponds to torus invariant divisors $V(\rho)$, generating the class group, which intersects $U_\sigma \cap U_\tau$. Therefore, using the formula from Lemma 3.23, for all $\rho \subset \sigma \cap \tau$ we have $\langle m(\sigma), v_\rho \rangle = \langle m(\tau), v_\rho \rangle$ which implies that the linear functions $\langle m(\sigma), - \rangle$ glue to a support function $\psi : |\Sigma| \rightarrow \mathbb{R}$. \square

Finally, the notion of support functions gives a natural way to compute the dimensions of global section and associate torus-invariant Cartier divisors to rational polytopes. This notion will be of particular use for us as we make associations between curves and Newton polygons.

Theorem 3.1. Let D be a \mathbb{T} -invariant Weil divisor on $X = \mathbb{T}_\Sigma$. Then we may decompose the $T(N)$ -module $H^0(X, \mathcal{O}_X(D))$ as,

$$H^0(X, \mathcal{O}_X(D)) = \bigoplus_{\chi^u \in H^0(X, \mathcal{O}_X(D))} k \cdot \chi^u$$

Proof. The $T(N)$ -action on the k -vectorspace $H^0(X, \mathcal{O}_X(D))$ decomposes as the sum of eigenspaces by general representation theory of the torus $T(N)$. Then the characters $\chi^u \in K(X)$ are exactly these eigenfunctions of $T(N)$. For a detailed proof see [CLS11, Prop. 4.3.2]. \square

Lemma 3.27. Let D be Cartier then $\chi^u \in H^0(X, \mathcal{O}_X(D)) \iff \forall \rho \in \Sigma(1) : \langle u, v_\rho \rangle \geq \psi_D(v_\rho)$.

Proof. The characters χ^u are invertible rational functions $\chi^u \in K(\mathbb{T}_\Sigma)^\times$. By definition.

$$\chi^u \in H^0(X, \mathcal{O}_X(D)) \iff \operatorname{div}(\chi^u) + D \geq 0$$

However, we have computed,

$$\operatorname{div}(\chi^u) = \sum_{\rho \in \Sigma(1)} \langle u, v_\rho \rangle D_\rho$$

so by the definition of ψ_D we have,

$$\operatorname{div}(\chi^u) + D = \sum_{\rho \in \Sigma(1)} \langle u, v_\rho \rangle D_\rho + \sum_{\rho \in \Sigma(1)} -\psi_D(v_\rho) D_\rho \geq 0 \iff \langle u, v_\rho \rangle \geq \psi_D(v_\rho)$$

\square

Proposition 3.28. Let \mathbb{T}_Σ be a toric variety and D a torus-invariant Cartier divisor on \mathbb{T}_Σ . Then the associated polytope is,

$$P_D = \{m \in M_\mathbb{R} \mid \forall u \in |\Sigma| : \langle m, u \rangle \geq \psi_D(v_\rho)\} = \bigcap_{\rho \in \Sigma(1)} H^+(v_\rho, \psi_D(v_\rho))$$

Proof. By definition $m \in P_D \iff \forall \rho \in \Sigma(1) : \langle m, v_\rho \rangle \geq -a_\rho$ but $-a_\rho = \psi_D(v_\rho)$ so these agree because $u \in |\Sigma|$ there is some cone $u \in \sigma \in \Sigma$ so,

$$u = \sum_{\rho \in \sigma(1)} c_\rho v_\rho$$

for $c_\rho \geq 0$ then,

$$\langle m, u \rangle = \sum_{\rho \in \sigma(1)} c_\rho \langle m, v_\rho \rangle \geq \sum_{\rho \in \sigma(1)} c_\rho \psi_D(v_\rho) = \psi_D \left(\sum_{\rho \in \sigma(1)} c_\rho v_\rho \right) = \psi_D(u)$$

where the second to last equality follows from the fact that $\psi_D|_\sigma$ is linear. \square

Proposition 3.29. If \mathbb{T}_Σ is complete then P_D is bounded and thus a rational polytope.

Proof. \mathbb{T}_Σ is complete exactly when $|\Sigma| = N_\mathbb{R}$ in which case,

$$\operatorname{Cone}(\{v_\rho \mid \rho \in \Sigma(1)\}) = N_\mathbb{R}$$

Therefore, the vectors v_ρ span N with positive coefficients implying that P_D is bounded. \square

Proposition 3.30. For a torus-invariant Weil divisor, the polytopes P_D satisfy:

(a). $P_{D+\operatorname{div}(\chi^u)} = P - u$

(b). $P_{nD} = nP_D$

(c). $P_D + P_E \subset P_{E+D}$

(d). if $D \sim D'$ then $P_D \cong_t P_{D'}$ where \cong_t denotes translation congruence

(e). $\dim_k H^0(X, \mathcal{O}_X(D)) = |P \cap M|$

Proof. The first two three properties are an easy calculation. Part (d) follows from (a) since if $D \sim D'$ then $D = D' + \dim(\chi^u)$ since both are supported on the toric divisor so they must differ by the divisor of some character (it must have no poles or zeros on the torus). Thus, using (a) we see that P_D and $P_{D'}$ are translation equivalent. Then (e) follows from decomposition theorem of cohomology of torus-invariant divisors. Note that,

$$\chi^u \in H^0(X, \mathcal{O}_X(D)) \iff \operatorname{div}(\chi^u) + D \geq 0$$

but we have,

$$\operatorname{div}(\chi^u) + D = \sum_{\rho \in \Sigma(1)} [\langle u, v_\rho \rangle D_\rho + a_\rho D_\rho]$$

and thus,

$$\chi^u \in H^0(X, \mathcal{O}_X(D)) \iff \forall \rho \in \Sigma(1) : \langle n, v_\rho \rangle \geq -a_\rho \iff u \in P_D \cap M$$

Then $\chi^u \in H^0(X, \mathcal{O}_X(D)) \iff u \in P_D \cap M$ and thus gives a decomposition,

$$H^0(X, \mathcal{O}_X(D)) = \bigoplus_{u \in P_D \cap M} k \cdot \chi^u$$

□

Remark. For any divisor D there is a bounded convex body $\Delta(D)$ called the Okunkov body associated to D . However, this is not, in general, a lattice polytope. In the case that D is Cartier then $\Delta(D)$ and P_D are congruent.

Finally, we consider how positivity properties of divisors manifest in the toric fan data, especially the particularly important question of when the rational polytope P_D is actually integral.

Theorem 3.31. Let D be a torus-invariant Cartier divisor on \mathbb{T}_Σ where $|\Sigma|$ is concave of full dimension. Then the following hold:

(a). D is base-point-free ($\mathcal{O}_X(D)$ is globally generated) $\iff \psi_D$ is concave $\iff D$ is nef

(b). D is ample $\iff \psi_D$ is strictly concave

(c). when D is ample then ℓD is very ample for all $\ell \geq n - 1$ (assuming $n > 1$)

(d). P_D is an integral polytope when D is base-point free.

Proof. Use [CLS11, Thm. 6.1.10] and [CLS11, Thm. 6.1.15] and [CLS11, Thm. 7.22]. □

Remark. Note that what Cox calls a convex function is what we, believing it to be more standard notation, call a concave function. To explicitly clarify notation, here we say that a function φ on a convex set $\Omega \subset N_\mathbb{R}$ is *concave* if for any $x, y \in \Omega$ and $t \in (0, 1)$ then,

$$\varphi((1-t)x + ty) \geq (1-t)\varphi(x) + t\varphi(y)$$

and *strictly concave* if

$$\varphi((1-t)x + ty) > (1-t)\varphi(x) + t\varphi(y)$$

3.4 Construction of a Toric Divisor from a Rational Polytope

Definition 3.32. An integral or lattice polytope $P \subset M \otimes_{\mathbb{Z}} \mathbb{R}$ is the convex hull of a finite subset of M . Such a polytope has a representation as finite intersection of integral half-spaces,

$$P = \bigcap_F \{m \in M \mid \langle n_F, m \rangle \geq -a_F\}$$

where F are the facets of P and $u_F \in M^\vee$ and $a_F \in \mathbb{Z}$. We may assume that u_F is the minimal inward normal in M^\vee .

Definition 3.33. Given a lattice polytope $P \subset M_{\mathbb{R}}$ we define the *normal fan* $\Sigma_P \subset N_{\mathbb{R}}$ as follows. For each face $A \subset P$ (not necessarily a facet, not including $A = P$ but including $A = \emptyset$) define,

$$\sigma_A = \text{Cone}(\{n_F \mid F \subset P \text{ is a facet s.t. } A \subset F\})$$

Then let $\Sigma_P = \{\sigma_A \mid A \subset P \text{ is a face}\}$.

Proposition 3.34. Given a lattice polytope P , the set Σ_P is a fan in $N_{\mathbb{R}}$.

Proposition 3.35. There is a duality between P and Σ_P given the inclusion reversing correspondence $A \subset P \leftrightarrow \sigma_A \in \Sigma_P$ satisfying,

- (a). inclusion reversing, $A \subset B \iff \sigma_B \subset \sigma_A$
- (b). $\dim A + \dim \sigma_A = \dim P$

Proof. $A \subset B$ implies that if F is a face containing B then F contains A so $\sigma_B \subset \sigma_A$. Furthermore, a face $A \subset P$ is contained in exactly $\dim P - \dim A$ facets giving the second property. \square

Definition 3.36. Let P be a lattice polytope. Define the proper toric variety $X_P = X_{\Sigma_P}$. Via the above correspondence and the cone - orbit correspondence there is an inclusion preserving correspondence between dimension i faces $A \subset P$ and dimension i torus orbits. In particular,

- (a). vertices of $P \leftrightarrow$ fixed points of the torus action on X_P
- (b). facets of $P \leftrightarrow$ T-invariant irreducible divisors in X_P

Definition 3.37. Given a lattice polytope P , we construct a toric variety - toric divisor pair (X_P, D_P) via $X_P = X_{\Sigma_P}$ and summing over the facets $F \subset P$ take,

$$D_P = \sum_{\substack{F \subset P \\ \text{a facet}}} a_F V(\sigma_F)$$

Recall that if F is a facet then $\sigma_F \in \Sigma_P(1)$ so these are indeed prime divisors $D_F = V(\sigma_F)$.

Proposition 3.38. The divisor D_P is an ample Cartier divisor on X_P .

Proof. Let m be a vertex of P and σ_m the corresponding maximal cone. Now I claim that for any facet F ,

$$D_F \cap U_{\sigma_m} \neq \emptyset \iff m \in F$$

Indeed,

$$m \in F \iff \sigma_F \subset \sigma_m \iff \sigma_m \in \Sigma[\sigma_F] \iff D_F \cap U_{\sigma_m} \neq \emptyset$$

Therefore,

$$\operatorname{div}(\chi^{-m})|_{U_{\sigma_m}} = \sum_{m \in F} -\langle m, n_F \rangle D_F = \sum_{m \in F} a_F D_F = -D_P|_{U_{\sigma_m}}$$

because $\langle m, n_F \rangle = -a_F$ by the defining representation of P since m is a vertex and F is a facet containing m . Thus, D_P is Cartier since it is principal on the open cover of maximal cones. Therefore, we may consider ψ_D which satisfies $\psi_{D_P}|_{\sigma_m} = \langle m, - \rangle$. Finally, ψ_{D_P} is strictly concave meaning that D_P is ample by [CLS11, Thm. 6.1.15]. \square

Remark. Therefore we have a construction, given a lattice polytope P , of a proper toric variety $X_P = X_{\Sigma_P}$ of the normal fan. In fact, the following theorem classifies toric varieties arising from a normal fan.

Theorem 3.39. A toric variety X is protective iff $X = \mathbb{T}_P$ for some lattice polytope P i.e. if $X = \mathbb{T}_\Sigma$ where $\Sigma = \Sigma_P$ is the normal fan of some lattice polytope P . In fact, if D is an ample \mathbb{T} -invariant Cartier divisor (equivalently ψ_D is strictly-convex) on \mathbb{T}_Σ and $|\Sigma|$ is convex of full dimension then,

- (a). P_D is a full-dimensional lattice polytope
- (b). Σ is the normal fan of P_D .

Proof. We have seen that the associated divisor D_P on \mathbb{T}_P is ample so \mathbb{T}_P is quasi-projective, Furthermore, the normal fan has $|\Sigma_P| = N$ i.e. is a complete fan so \mathbb{T}_P is complete and thus projective. The second fact is given by [CLS11, Thm. 7.2.3]. Now if \mathbb{T}_Σ is projective then Σ is complex and there must be an ample Cartier divisor D on \mathbb{T}_Σ corresponding to some projective embedding. Replacing D by an equivalent \mathbb{T} -invariant ample Cartier divisor we may apply the second part to conclude that Σ is the normal fan of P_D . \square

Theorem 3.40. The polytope associated to the divisor D_P on \mathbb{T}_P is $P_{D_P} = P$ so the mapping,

$$\{(X, D) \mid X \text{ toric } \dim X = d \text{ and } D \text{ ample Cartier}\} \rightarrow \{\text{integral polytopes of dimension } d\}$$

sending projective toric varieties of dimension d with \mathbb{T} -invariant divisors to integral polytopes is surjective.

Proof. Recall that the cones $\rho \in \Sigma_P(1)$ correspond to facets $F \subset P$. The divisor D_P corresponds to the support function ψ_{D_P} with $\psi_{D_P}(v_\rho) = -a_F$. Therefore,

$$P_{D_P} = \bigcap_{\substack{F \subset P \\ \text{a facet}}} H^+(n_F, -a_F) = P$$

\square

3.5 Cohomology and Duality on Toric Varieties

The toric divisor $D_{\mathbb{T}}$ on $X = \mathbb{T}_\Sigma$ is especially important because it corresponds to the anticanonical divisor $-K_X$. Although toric varieties are not always smooth, complete toric varieties admit a good form of Serre duality because they are always Cohen-Macaulay by [CLS11, Thm 9.2.9]. In particular, there exists a dualizing sheaf ω_X on X and the natural maps $\operatorname{Ext}_{\mathcal{O}_X}^i(\mathcal{F}, \omega_X) \xrightarrow{\sim} H^{n-i}(X, \mathcal{F})^\vee$ is an isomorphism. In particular we can compute the dualizing sheaf in terms of a canonical divisor.

Lemma 3.41. The dualizing sheaf is $\omega_X = \mathcal{O}_X(K_X)$ where the canonical divisor is defined,

$$K_X = - \sum_{\rho \in \Sigma(1)} D_\rho$$

Proof. See [CLS11, Thm. 8.2.3]. □

Remark. The canonical divisor K_X is defined as a torus-invariant Weil divisor but it is not, in general, a Cartier divisor. Then K_X will be Cartier when the dualizing sheaf is a line bundle, in particular, when X is Gorenstein. In the toric case, we can describe combinatorially when K_X is Cartier which holds exactly when for each maximal cone $\sigma \in \Sigma(n)$ there exists $\exists m_\sigma \in M$ such that $\langle m_\sigma, v_\rho \rangle = 1$ for all rays $\rho \prec \sigma$ by [CLS11, Prop. 8.2.12].

We now turn our attention to the subject of vanishing theorems for cohomology on toric varieties. There is almost unending possibility for discussion of these vanishing results so we will not here attempt to give a comprehensive overview. Rather, we will discuss only the most widely applicable vanishing results and those which will be required in cohomology computations to follow. First, we sketch the proof of Demazure's vanishing theorem which takes a short detour into topological cohomology with supports.

Definition 3.42. Let D be a \mathbb{T} -invariant Cartier divisor then,

$$Z_D(u) = \{v \in |\Sigma| \mid \langle u, v \rangle \geq \psi_D(v)\}$$

which is a closed cone equal to a hull of cones in Σ .

Corollary 3.43. Let D be a torus-invariant Cartier divisor on \mathbb{T}_Σ then,

$$\chi^u \in H^0(X, \mathcal{O}_X(D)) \iff Z_D(u) = |\Sigma|$$

Example 3.44. If $\Sigma = \sigma$ then

$$H^0(\mathbb{T}_\sigma, \mathcal{O}_{\mathbb{T}_\sigma}(D)) = \bigoplus k \cdot \chi^u$$

where u is such that $Z_D(u) \cap |\sigma| = |\sigma|$.

Definition 3.45. Let X be a topological space and \mathcal{F} a sheaf on X . For $Z \subset X$ define the sections over U of \mathcal{F} with support in Z is,

$$H_Z^0(U, \mathcal{F}) = \{s \in H^0(U, \mathcal{F}) \mid \forall V \subset U \cap (X \setminus Z) : s|_V = 0\}$$

If $Z \subset M$ is closed then $H_Z^0(U, \mathcal{F}) = \ker(H^0(U, \mathcal{F}) \rightarrow H^0(U \setminus Z, \mathcal{F}))$.

Example 3.46. If $X = |\Sigma|$ and $\mathcal{F} = \underline{k}$ then consider the cases,

- (a). $Z \subsetneq |\Sigma|$ in which case, let $s \in H^0(|\Sigma|, \underline{k})$ but $|\Sigma|$ is path-connected (it is star shaped at zero) so $H^0(|\Sigma|, \underline{k}) = k$. Thus if $s|_V = 0$ then $s = 0$ as long as $V \neq \emptyset$. Thus $H_Z^0(|\Sigma|, \underline{k}) = 0$.
- (b). $Z = |\Sigma|$ in which case $H_Z^0(|\Sigma|, \underline{k}) = H^0(|\Sigma|, \underline{k}) = k$.

Proposition 3.47. Using the above calculations, we see that, $H^0(\mathbb{T}_\Sigma, \mathcal{O}_{\mathbb{T}_\Sigma}(D))_u = H_{Z_D(u)}^0(|\Sigma|, \underline{k})$.

Definition 3.48. Consider the functor $H_Z^0(U, -)$ which has p^{th} -derived functors $H_Z^p(U, -)$ called cohomology with support in Z .

Theorem 3.49. Let D be a \mathbb{T} -invariant Cartier divisor on $X = \mathbb{T}_\Sigma$. There is a canonical decomposition,

$$H^p(X, \mathcal{O}_X(D)) = \bigoplus_{u \in M} H_{Z_D(u)}^p(|\Sigma|, \underline{k})$$

where we write, $H^p(X, \mathcal{O}_X(D))_u = H_{Z(u)}^p(|\Sigma|, \underline{k})$.

Proof. Since on the affine open cover $\{U_\sigma\}$ we can by the above arguments show that $H^0(U_\sigma, \mathcal{O}_X(D))_u = H_{Z_D(u)}^0(|\text{Star}(\sigma)|, \underline{k})$. Then taking the Čech complex for $\mathcal{O}_X(D)$ with the cover $\{U_\sigma\}$ gives a complex which computes the cohomology $H_{Z_D(u)}^p(|\Sigma|, \underline{k})$. See the proof of [CLS11, Thm. 9.1.2] and the succeeding discussion for a detailed argument. \square

Corollary 3.50. If ψ_D is concave then $H^p(X, \mathcal{O}_X(D)) = 0$ for all $p > 0$.

Proof. Apply the long exact sequence for cohomology with support on a closed $Z \subset X$,

$$\begin{array}{ccccccc} 0 & \longrightarrow & H_Z^0(X, \mathcal{F}) & \longrightarrow & H^0(X, \mathcal{F}) & \longrightarrow & H^0(U, \mathcal{F}|_U) \\ & & & & & & \downarrow \\ & & & & & & H^1(X, \mathcal{F}) \longrightarrow H^1(U, \mathcal{F}|_U) \\ & & & & & & \downarrow \\ & & & & & & H^2(X, \mathcal{F}) \longrightarrow H^2(U, \mathcal{F}|_U) \longrightarrow \dots \end{array}$$

to the case $X = |\Sigma|$ and $Z = Z_D(u)$ and $\mathcal{F} = \underline{k}$. The open,

$$U = X \setminus Z = |\Sigma| \setminus Z_D(u) = \{v \in |\Sigma| \mid \langle u, v \rangle < \psi_D(v)\}$$

is convex because $\langle u, - \rangle - \psi_D$ is convex and thus its sublevel sets are convex. Now apply the long exact sequence noting that $H^p(|\Sigma|, \underline{k}) = 0$ and $H^p(|\Sigma| \setminus Z_D(u), \underline{k}) = 0$ for $p > 0$ since both are contractible. Thus $H_{Z_D(u)}^p(|\Sigma|, \underline{k}) = 0$ for $p > 1$. Furthermore, $H_{Z_D(u)}^1(|\Sigma|, \underline{k}) = 0$ since the map $H^0(|\Sigma|, \underline{k}) \rightarrow H^0(|\Sigma| \setminus Z_D(u), \underline{k})$ is surjective when both sets are connected. \square

Combining this result with our previous correspondence between base-point-free Cartier divisors and concave support functions gives Demazure's celebrated vanishing theorem.

Theorem 3.51 (Demazure Vanishing). Let D be a \mathbb{T} -invariant base-point-free Cartier divisor (i.e. $\mathcal{O}_X(D)$ is a line bundle generated by global sections). Then,

$$H^p(X, \mathcal{O}_X(D)) = 0 \quad \text{for all } p > 0$$

We now conclude this section with the statement of a toric version of Kodaira' vanishing theorem.

Theorem 3.52 (Kodaira Vanishing). Let D be an ample Cartier divisor on a complete toric variety $X = \mathbb{T}_\Sigma$. Then,

$$H^p(X, \omega_X(D)) = H^p(X, \mathcal{O}_X(K_X + D)) = 0 \quad \text{for all } p > 0$$

Proof. Let D be ample Cartier divisor which we may assume is \mathbb{T} -invariant since the result holds up to linear equivalence. Note that $K_X + D$ may fail to be Cartier when X is not Gorenstein. However, by Serre duality, the theorem is equivalent to $H^{n-p}(X, \mathcal{O}_X(-D)) = 0$. Since D is Cartier,

$$H^{n-p}(X, \mathcal{O}_X(-D)) = \bigoplus_{m \in M} H_{Z_{-D}(u)}^{n-p}(|\Sigma|, \underline{k})$$

which reduces to a combinatorial argument to show $H_{Z_{-D}(u)}^{n-p}(|\Sigma|, \underline{k}) = 0$ for $p > 0$ and ψ_D concave since D is ample Cartier. This result goes by the name, the Batyrev-Borisov Vanishing Theorem [CLS11, Thm. 92.7] which generalizes the result to when D is nef. \square

4 Curves in Toric Surfaces

4.1 Introduction

In this section, we are motivated by the following basic question: given a smooth complete curve C and a toric surface S , when does there exist a closed immersion $C \hookrightarrow S$? Likewise for the smooth complete curve C , we consider when there exists some toric surface S with a closed immersion $C \hookrightarrow S$? This question may be motivated by the toric construction of regular normal crossings models of a curve described by [Dok18] which requires the curve and various modifications of it to admit embeddings and smooth compactifications in specific toric surfaces. It turns out the very general answer to both questions will be negative. However, for curves which do admit such a toric embedding, we get a strong theory relating the possible toric embeddings to numerical invariants of the curve C as an extension of the well-known numerical constraints on the genus of plane curves. As a first step to understanding embeddings $C \hookrightarrow S$, notice there are two cases, either C intersects the torus $\mathbb{G}_{m,k}^2 \hookrightarrow S$ or the image of C in S is contained in the toric divisor $D_{\mathbb{T}} = \bigcup C_i$ which is a union of curves which are toric varieties. In the later case, since the curve C is irreducible, such an embedding gives an isomorphism between C and an irreducible component of the toric divisor C_i but toric varieties are clearly rational so this case can only occur when C is rational. We will generally ignore this possibility since \mathbb{P}_k^1 is the unique smooth complete rational curve. Therefore, we get a trivial positive answer for rational curves since \mathbb{P}_k^1 is the unique one dimensional toric variety so \mathbb{P}_k^1 can always be embedded in the toric divisor of any toric surface.

Thus, when C is non-rational, any embedding $C \hookrightarrow S$ into a toric surface S must intersect the torus $\mathbb{G}_{m,k}^2 \subset S$ giving a closed immersion $U \hookrightarrow \mathbb{G}_{m,k}^2$ of some open affine $U \subset C$. Therefore, our first task will be to understand closed immersions of affine curves $U \hookrightarrow \mathbb{G}_{m,k}^2$.

Lemma 4.1. Every geometrically reduced curve over k is birational to some $U_f \hookrightarrow \mathbb{G}_{m,k}^2$.

Proof. Let C be a curve over k . Then $\dim C = \text{trdeg}_k(K(C))$ by Noetherian normalization so there is a transcendental $t \in K(C)$ such that $K(C)$ is finite over $k(t)$. If we assume that $K(C)/k(t)$ is separable then by the primitive element theorem $K(C) = k(t)[x]/(m(x)) = \text{Frac}(k[t^{\pm 1}, x^{\pm 1}]/(m(x)))$ for the minimal polynomial x of the primitive element. Such an isomorphism identifies open subsets of C and of $\text{Spec}(k[t, x]/(m(x))) \hookrightarrow \mathbb{G}_{m,k}^2$.

To see why $K(C)/k(t)$ is separable we use the fact that X is geometrically reduced. In particular the k -algebra $K(C)$ is geometrically reduced or equivalently $K(C)/k$ is a (transcendental) separable extension of fields (see Tag 030W) which implies that $K(C)/k(t)$ is a finite separable extension (in the usual sense) of fields. \square

Remark. When k is perfect, we can show that any curve C over k is geometrically reduced (Tag 020I), in particular $k(C)$ is separable for any curve C over k . However, when k is non-perfect, there are examples of degree one transcendental extensions which are not separable over k . For example, take $k = \mathbb{F}_p(t)$ and $K(C) = k(x, t^{1/p})$ which is not separable over k and in fact $K(C)$ is not a primitive extension of k .

However, it does not suffice to take *any* affine open as the following example shows, we must indeed take a sufficiently small open so the notion of birationality here is actually necessary.

Proposition 4.2. There exists a smooth affine curve C over k with no closed immersion $C \hookrightarrow \mathbb{G}_{m,k}^2$.

Proof. We use the obstruction that any curve embedded in $\mathbb{G}_{m,k}^2$ must have a trivial canonical bundle (Lemma 4.3). Therefore, it suffices to produce a smooth affine curve with a nontrivial canonical bundle. The affiness is easy to arrange since for any smooth complete curve \overline{C} then removing a single point leaves an affine curve (Lemma 4.4). Setting $C = \overline{C} \setminus \{P\}$, the inclusion $j : C \rightarrow \overline{C}$ induces an exact sequence,

$$\mathbb{Z} \longrightarrow \text{Cl}(\overline{C}) \xrightarrow{j^*} \text{Cl}(C) \longrightarrow 0$$

where the first map is $1 \mapsto [P]$. Therefore, a divisor class D is sent to zero under $f^*D \sim 0$ iff $D \sim \deg D \cdot [P]$. We need to show that the canonical divisor does not vanish $K_C \not\sim 0$ and thus that $K_{\overline{C}} \not\sim (2g-2) \cdot [P]$ since $j : C \hookrightarrow \overline{C}$ is étale so $\Omega_{C/k} = f^*\Omega_{\overline{C}/k}$. Therefore, it suffices to produce a curve \overline{C} with a point $P \in \overline{C}$ such that $K_{\overline{C}} \not\sim (2g-2) \cdot [P]$. Note that because the $(2g-2)$ -torsion in the Picard group for $g \geq 2$ is a finite group, all but finitely many choices for P on any smooth complete curve of genus $g \geq 2$ will work.

Specifically, take $\overline{C} = \text{Proj}(k[X, Y, Z]/(X^4 - X^2Z^2 + (Y - Z)^4 - Z^4))$ which is easily verified to be smooth in characteristic $p \neq 2, 5$ and has genus $g = 3$ since it is a plane curve of degree 4 in $X = \mathbb{P}_k^2$. Then choose $P = [0 : 0 : 1]$. Notice that under $\iota : \overline{C} \hookrightarrow \mathbb{P}_k^2$ we have $\Omega_{\overline{C}/k} \cong \iota^*\mathcal{O}_X(1)$ by the adjunction formula. We need to check that $(2g-2) \cdot [P]$ is not one of the effective divisors linearly equivalent to $K_{\overline{C}}$. Such divisors are parameterized by sections $H^0(\overline{C}, \Omega_{\overline{C}/k}) = H^0(X, \iota_*\iota^*\mathcal{O}_X(1))$. By the projection formula $\iota_*\iota^*\mathcal{O}_X(1) = \iota_*\mathcal{O}_{\overline{C}} \otimes_{\mathcal{O}_X} \mathcal{O}_X(1)$. To compute the sections of this coherent \mathcal{O}_X -module we apply the exact sequence of the Cartier divisor \overline{C} twisted by $\mathcal{O}_X(1)$,

$$0 \longrightarrow \mathcal{O}_X(-3) \longrightarrow \mathcal{O}_X(1) \longrightarrow \iota_*\mathcal{O}_{\overline{C}} \otimes_{\mathcal{O}_X} \mathcal{O}_X(1) \longrightarrow 0$$

and applying cohomology,

$$H^0(X, \mathcal{O}_X(-3)) \longrightarrow H^0(X, \mathcal{O}_X(1)) \longrightarrow H^0(\overline{C}, \iota^*\mathcal{O}_X(1)) \longrightarrow H^1(X, \mathcal{O}_X(-3))$$

but $H^q(X, \mathcal{O}_X(-3)) = 0$ for $q \leq 1$ so the map $H^0(X, \mathcal{O}_X(1)) \rightarrow H^0(\overline{C}, \iota^*\mathcal{O}_X(1))$ given by pulling back sections, $s \mapsto \iota^*s$, is bijective. In particular, since any section $s \in H^0(\overline{C}, \Omega_{\overline{C}/k})$ is the pullback of some hyperplane equation $h \in H^0(X, \mathcal{O}_X(1))$, the divisor of zeros associated to s is the hyperplane section $\iota^{-1}(H) = \overline{C} \cap H$ with the hyperplane $H = V(h)$. However, I claim that any line passing through P intersects \overline{C} in more than one point. To see this, consider the tangent line L to \overline{C} at P is $\mathbb{P}_k^1 \rightarrow X$ given by $[T_0 : T_1] \mapsto [T_0 : 0 : T_1]$ but $L \cap \overline{C} = \{[0 : 0 : 1], [1 : 0 : 1], [-1 : 0 : 1]\}$. Therefore, there cannot be any line passing through only P meaning that $\{P\}$ cannot be the support of any effective divisor in canonical linear system $H^0(\overline{C}, \Omega_{\overline{C}/k})$. Thus, $K_{\overline{C}} \not\sim (2g-2) \cdot [P]$ so $C = \overline{C} \setminus \{P\}$ has nontrivial canonical bundle yet is affine providing the required example. \square

Remark. Notice that although C is not an affine plane curve (in the sense of having a closed immersion $C \hookrightarrow D(q) \subset \mathbb{A}_k^2$ to some principal affine open) there is an immersion $C \hookrightarrow \mathbb{P}_k^2$ since $\overline{C} \hookrightarrow \mathbb{P}_k^2$ is a complete plane curve.

We conclude by providing proofs of the required lemmas.

Lemma 4.3. Let $C \hookrightarrow D(q) \subset \mathbb{A}_k^2$ be a smooth curve embedded in some standard open $D(q)$ in the affine plane. Then the canonical bundle $\Omega_{C/k}^1 \cong \mathcal{O}_C$ is trivial.

Proof. Let $A = k[x, y, q^{-1}]$ so $D(q) = \text{Spec}(A)$. Note that $C = \text{Spec}(R)$ with $R = A/I$ where $I = \ker(A \rightarrow \Gamma(C, \mathcal{O}_C))$. Furthermore, $I = (f)$ since $\dim C = 1$ thus $\text{ht}(I) = 1$ but C is irreducible and thus I is prime and since A is a UFD, $I = (f)$ since each height one prime is principal.

Furthermore, C is smooth so $(f, f_x, f_y) = A$ where f_x, f_y are the partial derivatives of f with respect to x and y . Therefore, we can choose $g, h \in A$ such that $gf_x + hf_y = 1$ in R . Now, consider the R -module of differentials, $\Omega_{R/k} = (Rdx \oplus Rdy)/(f_x dx + f_y dy)$.

Consider the map $\phi : R \rightarrow \Omega_{R/l}$ sending $1 \mapsto hdx - gdy$. Note that,

$$dx = gf_x dx + hf_y dx = hf_y dx - gf_y dy \implies f_y \mapsto dx$$

$$dy = gf_x dy + hf_y dy = gf_x dy - hf_x dx \implies -f_x \mapsto dy$$

so ϕ is surjective. Furthermore, suppose that $\phi(a) = 0$ then $\phi(f_x a) = \phi(f_y a) = 0$ so in $Rdx \oplus Rdy$ we have $adx, ady \in (f_x dx + f_y dy)$ meaning $adx = c_1(f_x dx + f_y dy)$ and $ady = c_2(f_x dx + f_y dy)$ giving $c_1 f_y = 0$ and $c_2 f_x = 0$ and $c_1 f_x = c_2 f_y = a$ since $Rdx \oplus Rdy$ is free. But then

$$a = gf_x a + hf_y a = gf_x c_2 f_y + hf_y c_1 f_x = 0$$

since $c_2 f_x = c_1 f_y = 0$ so ϕ is injective. Thus $\Omega_{R/k} \cong R$ and sheafifying gives, $\Omega_{C/k} \cong \mathcal{O}_C$. \square

Lemma 4.4. Let C be a smooth proper curve and $P \in C$ a point. Then $C \setminus \{P\}$ is affine.

Proof. The divisor $D = \nu[P]$ is very ample for sufficiently large ν (in fact for $\nu \geq 2g + 1$) [Har77, Thm. IV.3.2]. Therefore, the linear system $|\nu[P]|$ defines a closed (C is proper) immersion $j : C \hookrightarrow \mathbb{P}_k^{\nu-1}$ such that $\mathcal{O}_C(D) = j^* \mathcal{O}_{\mathbb{P}_k^{\nu-1}}(1)$ with the hyperplane sections pulling back to a basis of $H^0(C, \mathcal{O}_C(D))$. Since D is effective, there is some section $s \in H^0(C, \mathcal{O}_C(D))$ with $V(s) = \{P\}$ and thus some hyperplane section $h \in H^0(\mathbb{P}_k^{\nu-1}, \mathcal{O}_{\mathbb{P}_k^{\nu-1}}(1))$ with $s = j^* h$ and thus $\{P\} = j^{-1}(H \cap j(C))$ where $H = V(h) \subset \mathbb{P}_k^{\nu-1}$. Finally, $C \setminus \{P\} = j^{-1}(\mathbb{P}_k^{\nu-1} \setminus H)$ which is affine since j is a closed immersion and thus affine and the complement of a hyperplane in projective space is a standard open. \square

4.2 Very General Curves Do Not Live on Toric Surfaces

QUESTION 4.5. In this section I did everything for $k = \mathbb{C}$ since this is what is given in Harris-Mumford. Can we extend this to other fields?

QUESTION 4.6. I assumed that the toric surface S is smooth here for two reasons. (1) to ensure that $\mathbf{Pic}_{X/k}$ exists and (2) such that $C \hookrightarrow S$ is Cartier. Can we drop this assumption?

Here, we investigate the behavior of very general curves with respect to embeddings onto smooth toric surfaces. Our result is that for sufficiently large genus, very general curves cannot embed in any smooth toric surface. Intuitively, a very general curve is a curve the coefficients of whose defining equations do not satisfy any algebraic relations over \mathbb{Q} . Specifically, we define a very general curve as follows.

Definition 4.7. We say a smooth proper curve C over \mathbb{C} with genus g is *very general* if its class $[P] \in \mathcal{M}_g$ in the moduli space of smooth proper curves of genus g does not lie in any proper subvariety of \mathcal{M}_g defined over \mathbb{Q} .

To prove the required result, we will make use of the following theorem of Harris and Mumford which restricts the birationality classes of surfaces on which nontrivial families of very general curves lie.

Theorem 4.8 (Harris-Mumford). Let C be a generic curve of genus $g \geq 23$ and S an algebraic surface containing C such that C moves in a nontrivial linear system on S meaning that $\dim H^0(S, \mathcal{O}_S(C)) > 1$. Then S is a ruled surface birational to $C \times \mathbb{P}^1$.

Proof. See the introduction of [?]. □

Beyond this, we need a short foray into the theory of Picard schemes. Grothendieck introduced the notion of Picard schemes in two 1962 Bourbaki talks [Gro62] which generalizes the Picard group of X to a group scheme representing a Picard functor over X . First, we need a relative notion of the Picard group.

Definition 4.9. Let $f : X \rightarrow S$ be a morphism of schemes. Then we define the relative Picard group,

$$\mathrm{Pic}(X/S) = H^0(S, R^1 f_* \mathcal{O}_X^\times)$$

In particular, if $S = \mathrm{Spec}(k)$ then $\mathrm{Pic}(X/S) = H^1(X, \mathcal{O}_X^\times) = \mathrm{Pic}(X)$.

Lemma 4.10. Let $f : X \rightarrow S$ be a morphism with $f^\# : \mathcal{O}_S \xrightarrow{\sim} f_* \mathcal{O}_X$ then the sequence,

$$0 \longrightarrow \mathrm{Pic}(S) \longrightarrow \mathrm{Pic}(X) \longrightarrow \mathrm{Pic}(X/S) \longrightarrow H^2(S, f_* \mathcal{O}_X^\times) \longrightarrow H^2(X, \mathcal{O}_X^\times)$$

from the low-degree terms of the Leray spectral sequence is exact. When f admits a section $S \rightarrow X$ i.e. an S -point, then $H^2(X, S) \rightarrow$ is an isomorphism so,

$$\mathrm{Pic}(X/S) \cong \frac{\mathrm{Pic}(X)}{\mathrm{Pic}(S)}$$

Proof. The Leray spectral sequence gives an exact sequence of low degree terms,

$$\begin{array}{ccccccccc} 0 & \longrightarrow & H^1(S, f_* \mathcal{O}_X^\times) & \longrightarrow & H^1(X, \mathcal{O}_X^\times) & \longrightarrow & H^0(S, R^1 f_* \mathcal{O}_X^\times) & \longrightarrow & H^2(S, f_* \mathcal{O}_X^\times) & \longrightarrow & H^2(X, \mathcal{O}_X^\times) \\ & & \parallel & & \parallel & & \parallel & & \parallel & & \parallel \\ 0 & \longrightarrow & \mathrm{Pic}(S) & \longrightarrow & \mathrm{Pic}(X) & \longrightarrow & \mathrm{Pic}(X/S) & \longrightarrow & H^2(S, \mathcal{O}_S^\times) & \longrightarrow & H^2(X, \mathcal{O}_X^\times) \end{array}$$

A section $s : S \rightarrow X$ meaning $f \circ s = \mathrm{id}_S$ gives a left-inverse $s^* : H^p(X, \mathcal{O}_X^\times) \rightarrow H^p(S, \mathcal{O}_S^\times)$ to the map $f^* : H^p(S, \mathcal{O}_S^\times) \rightarrow H^p(X, \mathcal{O}_X^\times)$. In particular, the final map of the exact sequence is injective giving the require short exact sequence. □

Definition 4.11. Let X be a scheme over S . Then for any S -scheme $T \rightarrow S$ there is a map $\mathrm{Pic}(T) \rightarrow \mathrm{Pic}(X \times_S T)$ induced by the projection. Therefore, we may define the Picard presheaf on the big étale site,

$$\mathrm{Pic}_{X/S} : (\mathbf{Sch}_S)_{\mathrm{\acute{e}t}}^{\mathrm{op}} \rightarrow \mathbf{Ab} \quad T \mapsto \mathrm{Pic}(X \times_S T/T)$$

and $\mathrm{Pic}_{X/S}^{\mathrm{\acute{e}t}}$ the associated sheaf for the étale topology. If it exists, the Picard scheme $\mathbf{Pic}_{X/S}$ is the unique scheme representing this sheaf,

$$\mathrm{Hom}_S(-, \mathbf{Pic}_{X/S}) = \mathrm{Pic}_{X/S}^{\mathrm{\acute{e}t}}$$

Remark. In particular,

$$\mathbf{Pic}_{X/S}(S) = \mathrm{Hom}_S(S, \mathbf{Pic}_{X/S}) = \mathrm{Pic}(X \times_S S/S) = \mathrm{Pic}(X/S)$$

so for $S = \mathrm{Spec}(k)$ the k -points of $\mathbf{Pic}_{X/S}$ are exactly $\mathrm{Pic}(X)$.

In his Bourbaki talk, Grothendieck gave conditions for the Picard scheme to exist and relations between the geometry of $\mathbf{Pic}_{X/S}$ and cohomological invariants of line bundles.

Theorem 4.12 (FGA V. Thm. 3.1). Let $f : X \rightarrow S$ be a morphism of locally Noetherian schemes which is

- (a). projective
- (b). flat
- (c). fiberwise geometrically integral.

Then $\mathbf{Pic}_{X/S}$ exists.

The topology of the Picard scheme is related to a powerful equivalence relation on line bundles known as algebraic equivalence which is the algebraic version of topological homotopy equivalences of bundles.

Definition 4.13. Let X be a scheme over S . We say that $\mathcal{L}_1, \mathcal{L}_2 \in \text{Pic}(X)$ are *algebraically equivalent* $\mathcal{L}_1 \sim \mathcal{L}_2$ if there is a *connected* scheme T over S , closed points $t_1, t_2 \in T$, and a line bundle $\mathcal{L} \in \text{Pic}(X \times_S T)$ such that $\mathcal{L}|_{X \times \{t_1\}} \cong \mathcal{L}_1$ and $\mathcal{L}|_{X \times \{t_2\}} \cong \mathcal{L}_2$.

Proposition 4.14. Let $\mathbf{Pic}_{X/k}^0 \hookrightarrow \mathbf{Pic}_{X/k}$ be the connected component of the identity. Then $\mathbf{Pic}_{X/k}^0(k)$ is exactly the group of line bundles $\mathcal{L} \in \text{Pic}^0(X)$ algebraically equivalent to zero.

Proof. Let $\mathcal{L}_1, \mathcal{L}_2 \in \text{Pic}(X)$ be algebraically equivalent. Then the line bundle $\mathcal{L} \in \text{Pic}(X \times_k T)$ defines (up to an element of $\text{Pic}(T)$) a morphism $T \rightarrow \mathbf{Pic}_{X/k}$ then $\mathcal{L}_1 \cong \mathcal{L}|_{X \times \{t_1\}}$ and $\mathcal{L}_2 \cong \mathcal{L}|_{X \times \{t_2\}}$ are the pullback under the inclusions $\text{Spec}(\kappa(t_i)) \hookrightarrow T$ i.e. \mathcal{L}_i correspond to the points $\text{Spec}(\kappa(t_i)) \rightarrow \mathbf{Pic}_{X/k}$. However, T is connected so its image under $T \rightarrow \mathbf{Pic}_{X/k}$ is connected as well so the points $\text{Spec}(\kappa(t_i)) \rightarrow \mathbf{Pic}_{X/k}$ corresponding to \mathcal{L}_i under the identification $\mathbf{Pic}_{X/k}(k) = \text{Pic}(X)$ lie in the same connected component. \square

Remark. From the above discussion, we can define the Neron-Severi group $\text{NS}(S)$,

$$0 \longrightarrow \text{Pic}^0(X) \longrightarrow \text{Pic}(X) \longrightarrow \text{NS}(S) \longrightarrow 0$$

Therefore, the Neron-Severi group is the group of line bundles modulo algebraic equivalence or equivalently the group of connected components of $\mathbf{Pic}_{X/k}$.

Theorem 4.15. Let $X \rightarrow \text{Spec}(k)$ and assume that $\text{Pic}(X/k)$ exists representing $\text{Pic}_{X/k}^{\text{ét}}$. Then the Zariski tangent space at the trivial bundle has a canonical identification,

$$T_0 \mathbf{Pic}_{X/k} = H^1(X, \mathcal{O}_X)$$

thus $\dim \mathbf{Pic}_{X/k} \leq \dim_k H^1(X, \mathcal{O}_X)$ with equality exactly when $\mathbf{Pic}_{X/k}$ is smooth at 0. Since $\mathbf{Pic}_{X/k}$ is a group scheme, in this case $\mathbf{Pic}_{X/k}$ is everywhere smooth of dimension $\dim_k H^1(X, \mathcal{O}_X)$.

Proof. See [FSG⁺05, Thm. 5.11] and [FSG⁺05, Cor. 5.13]. \square

Remark. For a smooth proper curve C over k of genus g . Then $T_0 \mathbf{Pic}_{X/k} = H^1(X, \mathcal{O}_X)$ has dimension g so $\mathbf{Pic}_{X/k}^0$ is an abelian variety of dimension g which is the Jacobian variety of C .

Theorem 4.16. A generic curve over \mathbb{C} of genus $g \geq 23$ cannot embed into any smooth complete toric surface.

Proof. Given an embedding $C \hookrightarrow X$ into some toric surface $X = \mathbb{T}_\Delta$ we get $\mathbb{T}^2 \times_k C \hookrightarrow \mathbb{T}^2 \times_k X \rightarrow X$ giving a family of curves in X . Since C is non-rational, the embedding $C \hookrightarrow X$ cannot lie in the toric divisor and thus the family $\mathbb{T}^2 \times_k C \rightarrow X$ cannot be trivial since no point on the torus is a fixed point. Intuitively, the \mathbb{T}^2 -family of Cartier divisors $C \times_k \mathbb{T}^2 \rightarrow X$ defines a map $\mathbb{T}^2 \rightarrow \text{Pic}(X)$ via $t \mapsto \{t\} \times_k C \hookrightarrow X$. To make this rigorous, consider the multiplication map $m : X \times_k \mathbb{T}^2 \rightarrow X$ giving the following maps,

$$\text{Pic}(X) \rightarrow \text{Pic}(X \times_k \mathbb{T}^2) \xrightarrow{\sim} \text{Hom}_k(\mathbb{T}^2, \mathbf{Pic}_{X/k})$$

where the second is an isomorphism since $\text{Pic}(\mathbb{T}^2) = 0$. Then, the line bundle $\mathcal{L} = \mathcal{O}_X(C)$ defines a morphism $\mathbb{T}^2 \rightarrow \mathbf{Pic}_{X/k}$ which sends k -points $t \in \mathbb{T}^2$ to $\mathcal{L}_t \in \mathbf{Pic}_{X/k}(k)$ which is the line bundle $\mathcal{L}_t \cong \mathcal{O}_X(C_t)$ where C_t is the Cartier divisor defined by $m : \{t\} \times_k C \hookrightarrow X$. Since \mathbb{T}^2 is connected, all bundles \mathcal{L}_t lie in the same connected component $\mathbf{Pic}_{X/k}^0 \cdot \mathcal{L}$ which is a $\mathbf{Pic}_{X/k}^0$ -torsor. However, when X is rational $H^1(X, \mathcal{O}_X) = 0$ (in the toric case this is a simply application of Demazure's theorem) and thus $\dim \mathbf{Pic}_{X/k} = 0$ so the connected component $\mathbf{Pic}_{X/k}^0 = *$ is a single point, the trivial group scheme. Therefore, $\mathcal{L}_t \cong \mathcal{L}$ since any $\mathbf{Pic}_{X/k}^0$ -torsor is a single point. However, we have established that C_t form a nontrivial family of effective Cartier divisors which must correspond to sections $s_t \in H^0(X, \mathcal{O}_X(C))$ and thus $\dim_k H^0(X, \mathcal{O}_X(C)) \geq 2$.

Therefore, we may apply Harris-Mumford [HM82] to conclude that X is birational to $C \times_k \mathbb{P}_k^1$ for the general curve C . However, since X is toric it is rational, which implies, by the following Lemma, that $C \cong \mathbb{P}_k^1$ contradicting our assumption that $g > 0$. \square

Lemma 4.17. Let C be a smooth curve over $k = \mathbb{C}$. Then $C \times_k \mathbb{P}_k^1$ is unirational iff $C \cong \mathbb{P}_k^1$.

Proof. Suppose there is a dominant rational map $\mathbb{P}_k^2 \dashrightarrow C \times_k \mathbb{P}_k^1$. This gives a dominant rational map $\mathbb{P}_k^2 \dashrightarrow C$. Suppose that $g_C > 0$ then for any closed points $P, Q \in \text{Dom}(f)$ consider the line $L \subset \mathbb{P}_k^2$ through P, Q . Then $L \dashrightarrow C$ extends to a morphism $f : L \rightarrow C$ since these are proper curves with L smooth. However, if f is non-constant then, by Riemann–Hurwitz,

$$2g_L - 2 = (2g_C - 2) + \deg R$$

where R is the (effective) ramification divisor. But $2g_L - 2 = -2$ is negative and $(2g_C - 2) \geq 0$ and $\deg R \geq 0$. Thus $f : L \rightarrow C$ must be trivial so P, Q map to the same point of C contradicting the dominance of $\mathbb{P}_k^2 \dashrightarrow C$. Therefore we must have $g_C = 0$ in which case $C \cong \mathbb{P}_k^1$. To show this, consider the anticanonical divisor $D = -K_C$ with $\deg D = 2$. Then by Riemann Roch, since $\deg D > 1$, we know $\dim_k H^0(C, \mathcal{O}_C(D)) = 3$ and D is ample which defines a closed immersion $C \hookrightarrow \mathbb{P}_k^2$. However, for plane curves we have a formula,

$$g_C = \frac{1}{2}(d-1)(d-2)$$

so C is a plane conic but C has a k -rational point P since k is algebraically closed. Then projecting away from P gives a birational map $C \xrightarrow{\sim} \mathbb{P}_k^1$ which extends to an isomorphism $C \xrightarrow{\sim} \mathbb{P}_k^1$ since C is smooth. \square

4.3 Polytopes and Laurent Polynomials

In order to understand the moduli of curves which lie in toric surfaces, we would like to understand and develop a dictionary relating combinatorial features of defining data of a curve inside the torus to geometric properties of the complete curve inside the toric completion. This discussion relies upon the easy fact that curves inside the torus are defined uniquely up to unimodular transformation by Laurent polynomials which are objects well suited to description by combinatorial data.

Proposition 4.18. Curves $C_0 \subset \mathbb{G}_{m,k}^2$ are exactly $V(f)$ for some Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$ unique up to automorphism of the torus.

Proof. A closed immersion $C_0 \hookrightarrow \mathbb{G}_{m,k}^2$ is codimension 1 and thus is defined by some ideal $I \subset R = k[x^{\pm 1}, y^{\pm 1}]$ of height 1. Since C_0 is reduced we may take I to be radical and thus it is the intersection of the minimal primes \mathfrak{p} over I which have height one as well. Since R/I is Noetherian there are finitely many such minimal primes over I . Finally, since R is a UFD height one primes are principal and thus $I = \bigcap \mathfrak{p}_i = \bigcap (p_i) = (p_1 \cdots p_r)$ is principal and determined up to a unit in R corresponding to an automorphism of $\mathbb{G}_{m,k}^2$. \square

Given an irreducible Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$ we denote the associated curve in the torus $V(f) \subset \mathbb{G}_{m,k}^2$ by $U(f)$ following the notation of [Cas17].

Remark. Recall that the automorphism group of the n -torus $\text{Aut}(\mathbb{G}_{m,k}^n)$ is exactly $k^\times \times \text{GL}_n(\mathbb{Z})$ with the following action on coordinate ring $k[x_1^{\pm 1}, \dots, x_n^{\pm 1}]$,

$$(r, A) \cdot x_j = r \prod_{i=1}^n x_i^{a_{ij}} \quad \text{where} \quad r \in k^\times \quad \text{and} \quad A = (a_{ij}) \in \text{GL}_n(\mathbb{Z}) \quad (1)$$

Note that if we restrict to automorphism of the torus as a group scheme then $\text{Aut}(\mathbb{G}_{m,k}^n) = \text{GL}_n(\mathbb{Z})$ setting $r = 1$ and thus preserving the identity.

The most important combinatorial data which can be extracted from a Laurent polynomial is its Newton polygon.

Definition 4.19. Given a Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$, its Newton polygon $\Delta(f) \subset \mathbb{R}^2$ is the following convex polygon,

$$\Delta(f) = \text{Conv}(\{(i, j) \mid a_{ij} \neq 0\}) \quad \text{where} \quad f = \sum_{i,j} a_{ij} x^i y^j \quad (2)$$

Definition 4.20. For a convex rational polygon Δ we define,

$$\Delta^{(1)} = \text{Conv}(\Delta^\circ \cap \mathbb{Z}^2)$$

when Δ is a lattice polygon then $\Delta^{(1)}$ corresponds to shifting the faces of Δ inwards by one unit. Furthermore, if Γ is a polygon then let $\Gamma^{(-1)}$ be the *outward* shift by one unit (note $\Gamma^{(-1)}$ is a lattice polygon iff $\Gamma = \Delta^{(1)}$ for some lattice polygon Δ). Then we define $\Delta^{\max} = \Delta^{(1)(-1)}$.

We will begin our discussion of the combinatorial dictionary with the most fundamental question, when the complete curve inside the toric completion is smooth.

Definition 4.21. We say that $f \in k[x^{\pm 1}, y^{\pm 1}]$ is *nondegenerate with respect to its Newton polygon* if for each face $\tau \subset \Delta(f)$ (including $\Delta(f)$ itself then the Laurent polynomials,

$$f|_{\tau}, \partial_x f|_{\tau}, \partial_y f|_{\tau}$$

generate the unit ideal where we define restriction to a face $f|_{\tau}$ via the formula,

$$f|_{\tau} = \sum_{(i,j) \in \tau} a_{ij} x^i y^j \quad \text{where} \quad f = \sum_{(i,j) \in \Delta(f)} a_{ij} x^i y^j$$

For a fixed convex lattice polytope $\Delta \subset \mathbb{R}^2$ we say that f is Δ -nondegenerate if $\Delta(f) = \Delta$ and f is non-degenerate with respect to its Newton polygon.

This definition will be important in the context of the following construction which, given a Laurent polynomial f , constructs a smooth complete curve living on a toric surface birational to U_f via toric completion. However, some nondegeneracy condition on the defining Laurent polynomial will be necessary to ensure that the resulting complete curve is indeed smooth. We shall see that Δ -nondegeneracy will suffice. Abstractly, the construction goes as follows. Given a Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$ defining a curve $C_0 = U_f \subset \mathbb{G}_{m,k}^2$ and a convex lattice polytope Δ , consider the locally closed immersion $C_0 \hookrightarrow \mathbb{G}_{m,k}^2 \hookrightarrow \mathbb{T}_{\Delta}$ and let C_0^{Δ} be the scheme-theoretic image. Then clearly, C_0^{Δ} is a projective (and thus complete) curve on \mathbb{T}_{Δ} but it remains to see when C_0^{Δ} is smooth. We can describe this construction in a somewhat more geometrically satisfying way by considering the explicit projective embedding of the toric surface \mathbb{T}_{Δ} defined as follows. Let $N = |\Delta \cap \mathbb{Z}^2| - 1$ and consider the monomials $s_p = x^i y^j$ where $p = 0, 1, \dots, N$ indexes the lattice points $p(i, j) \in \Delta \cap \mathbb{Z}^2$. We consider these monomials as sections $s_p \in \Gamma(\mathbb{G}_{m,k}^2, \mathcal{O}_{\mathbb{G}_{m,k}^2})$ which trivially generate the structure sheaf and thus define a morphism $\mathbb{G}_{m,k}^2 \hookrightarrow \mathbb{P}^N$ which it is straightforward to verify is a locally closed immersion. Then \mathbb{T}_{Δ} is the scheme-theoretic image inside \mathbb{P}^N . Explicitly, the immersion $\psi : \mathbb{T}_{\Delta} \hookrightarrow \mathbb{P}^N$ is given by the linear system $|D_{\Delta}|$ for the divisor associated to the polytope Δ since these sections $x^i y^j$ for $(i, j) \in \Delta$ are exactly the characters $x^i y^j \in H^0(\mathbb{T}_{\Delta}, \mathcal{O}_{\mathbb{T}_{\Delta}}(D_{\Delta}))$. As we have seen (Proposition 3.38), the divisor D_{Δ} associated to Δ is strictly convex and thus ample (and globally generated) but for $n = \dim \mathbb{T}_{\Delta} = 2$ then D_{Δ} is very ample so $\mathbb{T}_{\Delta} \hookrightarrow \mathbb{P}^N$ is an immersion and $\mathcal{O}_{\mathbb{T}_{\Delta}}(D_{\Delta}) = \psi^* \mathcal{O}_{\mathbb{P}^N}(1)$. This map is always a closed embedding for proper toric surfaces, in general replacing a polygon P by $(n-1)P$ will make the immersion defined by the linear system $|D_P|$ into a closed immersion (Theorem 3.31 (c)). The curve C_0^{Δ} is then a hyperplane section of $\mathbb{T}_{\Delta} \subset \mathbb{P}^N$ defined by the hyperplane,

$$H_C = \sum_{(i,j) \in \Delta(f)} a_{ij} X_{ij} \quad \text{where} \quad f = \sum_{(i,j) \in \Delta(f)} a_{ij} x^i y^j$$

where \mathbb{P}^N is given coordinates X_{ij} for each $(i, j) \in \Delta$ and the map $\mathbb{G}_{m,k}^2$ may be described via the formula, $(x, y) \mapsto (X_{ij} = x^i y^j)$. Then it is clear that the vanishing of f extended to \mathbb{T}_{Δ} corresponds to the intersection of \mathbb{T}_{Δ} and the above hyperplane.

We can now give a geometric interpretation of the Δ -nondegenerate condition from the following proposition.

Proposition 4.22. A Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$ defining a torus curve $C_0 = U_f$ is Δ -nondegenerate exactly when for each face $\tau \subset \Delta$, the intersection of the complete curve C_0^{Δ} and the torus orbit $V(\tau)$ is smooth and of codimension 1 i.e. $\text{codim}(C_0^{\Delta} \cap V(\tau), V(\tau)) = 1$ and $C_0^{\Delta} \cap V(\tau)$ is smooth.

nondegenerate

weakly nondegenerate but not nondegenerate
(allowed to pass through non-singular \mathbb{T}^0 's,
tangency allowed to \mathbb{T}^1 's)

Figure 1: The intersection properties of a curve with the toric divisor distinguishes nondegeneracy from weak nondegeneracy. Specifically for the curve to be nondegenerate, it must meet the toric divisor transversally and away from the codimension two \mathbb{T} -invariant divisors (Image credit [Cas17]).

Proof. A full proof can be found in [Bat93, 3, Section 4], here we give a sketch. (GIVE SKETCH) \square

Note that this condition tells us about the nature of the intersection of the curve C_0^Δ and $\mathbb{T}_\Delta \setminus \mathbb{T}^2$. In particular, they must intersect transversally in order that the intersection be smooth and of codimension one. Furthermore, the vertices of Δ correspond to dimension zero orbits (which are the intersection of the irreducible components of $\mathbb{T}_\Delta \setminus \mathbb{T}^2$) and thus their intersection with C_0^Δ must be empty. Furthermore, since \mathbb{T}_Δ is always normal, smoothness in codimension one implies that the discussed intersection conditions are equivalent to those in the conclusion of the lemma. In summary, Δ -nondegenerate equations are those which define smooth curves in \mathbb{T}_Δ which intersects the toric boundary transversally and outside its intersection points.

This condition on the nature of the intersection with the toric boundary is less intrinsic to the curve (for example, fixing a $\mathbb{G}_{m,k}^2 \subset \mathbb{P}_k^2$ and a plane curve $C \subset \mathbb{P}_k^2$ we can always move the curve such that it intersects the three lines of the complement of the torus transversally and does not pass through the intersection points of these three lines) and will often be inconsequential for results we would like to prove about such objects. Thus we define the weaker notion which ignores this intersection criterion.

Definition 4.23. We say that a Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$ is Δ -toric if f defines a smooth curve $C_0 = U_f$ whose Δ -toric completion $C_0^\Delta \hookrightarrow \mathbb{T}_\Delta$ is smooth.

In the next section we will see how to reinterpret this condition purely in terms of properties of f , its Newton polygon, and the affine curve U_f .

4.4 Baker's Theorem on the Genus for Toric Embeddings

In this section, we discuss the classical result of Baker (1893) relating the genus of a smooth curve compactified in a toric surface to the enumerative properties of its associated convex lattice polygon.

Theorem 4.1 (Baker). Let $f \in k[x^{\pm 1}, y^{\pm 1}]$ be a Δ -nondegenerate Laurent polynomial. Then the toric completion $C_0^\Delta \hookrightarrow \mathbb{T}_\Delta$ of $C_0 = U_f$ is a smooth Cartier divisor on \mathbb{T}_Δ and thus C_0^Δ is the unique smooth proper curve birational to C_0 . Furthermore, the genus is computed via the number of interior lattice points of the Newton polygon,

$$g(C_0^\Delta) = |\Delta^\circ \cap \mathbb{Z}^2|$$

Proof. Since f is Δ -nondegenerate, then C_0^Δ is an integral codimension one closed subscheme which does not intersect the singular locus of \mathbb{T}_Δ (in particular, if $x \in C_0^\Delta$ then $\mathcal{O}_{\mathbb{T}_\Delta, x}$ is a UFD) so C_0^Δ is Cartier. Let $C = C_0^\Delta$ then to compute the genus of C we need to understand the space of sections of its canonical sheaf ω_C . Fixing notation, let $X = \mathbb{T}_\Delta$ and let $\iota : C \hookrightarrow X$ be the inclusion. Choose a torus-invariant Cartier divisor D_C linearly equivalent to the effective Cartier divisor C , in fact, we can explicitly write $D_C = C - \text{div}(f)$ which is torus-invariant because it is supported on the toric divisor since $C|_{\mathbb{T}^n} = \text{div}(f)|_{\mathbb{T}^n}$. We will now apply the adjunction exact sequence defined in Theorem 4.24,

$$0 \longrightarrow \omega_X \xrightarrow{f} \omega_X(D_C) \longrightarrow \iota_* \omega_C \longrightarrow 0$$

where the dualizing sheaf ω_C is, because C is smooth, is the canonical bundle. The cohomology long exact sequence gives,

$$0 \longrightarrow H^0(X, \omega_X) \longrightarrow H^0(X, \mathcal{O}_X(D_C + K_X)) \longrightarrow H^0(C, \omega_C) \longrightarrow H^1(X, \omega_X)$$

But $H^0(X, \omega_X) = H^0(X, \mathcal{O}_X(K_X)) = 0$ since the canonical divisor has an empty corresponding polytope $P_{K_X} = \emptyset$. Furthermore, $H^1(X, \omega_X) = H^0(X, \mathcal{O}_X) = 0$ by Serre duality and Demazure vanishing. Therefore, the cohomology sequence gives an isomorphism,

$$H^0(X, \mathcal{O}_X(D_C + K_X)) \xrightarrow{\sim} H^0(C, \omega_C)$$

In particular, the genus is,

$$g(C) = \dim_k H^0(X, \mathcal{O}_X(D_C + K_X)) = |P_{D_C + K_X} \cap \mathbb{Z}^2|$$

Thus, we need to compute P_{D_C} . Recall that under the embedding $\psi : \mathbb{T}_\Delta \hookrightarrow \mathbb{P}_k^N$ the curve C is the hyperplane section defined by the hyperplane,

$$H_C = \sum_{(i,j) \in \Delta} a_{ij} X_{ij} \quad \text{where} \quad f = \sum_{(i,j) \in \Delta} a_{ij} x^i y^j$$

Therefore, $\mathcal{O}_X(C) = \psi^* \mathcal{O}_{\mathbb{P}^N}(H_C) \cong \psi^* \mathcal{O}_{\mathbb{P}^N}(1)$ but recall that $\mathcal{O}_X(D_\Delta) = \psi^* \mathcal{O}_{\mathbb{P}^N}(1)$ so we find that $\mathcal{O}_X(C) \cong \mathcal{O}_X(D_\Delta)$. Therefore, $D_C \sim C \sim D_\Delta$ but both D_C and D_Δ are torus-invariant so $P_{D_C} \cong_t \Delta$ (using that $P_{D_\Delta} = \Delta$). Decomposing,

$$\Delta = \bigcap_{\substack{F \subset \Delta \\ \text{facet}}} H^+(n_F, -a_F)$$

we find,

$$D_C \sim \sum_{\substack{F \subset \Delta \\ \text{facet}}} a_F D_F$$

Recall the canonical divisor is,

$$K_X = - \sum_{\substack{F \subset \Delta \\ \text{facet}}} D_F$$

Thus,

$$D_C + K_X \sim \sum_{\substack{F \subset \Delta \\ \text{facet}}} (a_F - 1) D_F$$

which implies that,

$$P_{D_C + K_X} \cong_t \bigcap_{\substack{F \subset \Delta \\ \text{facet}}} H^+(n_F, 1 - a_F) = \Delta^{(1)}$$

since Δ is a lattice polygon. Therefore, we conclude,

$$g(C) = |\Delta^{(1)} \cap \mathbb{Z}^2| = |\Delta^\circ \cap \mathbb{Z}^2|$$

□

(RELATE THIS ABOVE FACT TO CANONICAL EMBEDDING)

Theorem 4.24. Let X be a normal projective Cohen-Macaulay variety, and $\iota : C \hookrightarrow X$ a divisor, and $D_C = C - \text{div}(f)$ a linearly equivalent Weil divisor. Then there is an exact sequence,

$$0 \longrightarrow \omega_X \xrightarrow{f} \omega_X(D_C) \longrightarrow \iota_* \omega_C \longrightarrow 0$$

Proof. The sheaf $\mathcal{O}_X(-D_C)$ is isomorphic to the sheaf of ideals defining $\iota : C \hookrightarrow X$ giving an exact sequence,

$$0 \longrightarrow \mathcal{O}_X(-D_C) \xrightarrow{f} \mathcal{O}_X \longrightarrow \iota_* \mathcal{O}_C \longrightarrow 0$$

Note that when $C \hookrightarrow X$ is an effective Cartier divisor then $\mathcal{O}_X(-D_C)$ is its defining invertible sheaf of ideals. Applying the functor $\mathcal{H}om_{\mathcal{O}_X}(-, \omega_X)$ to the above short exact sequence gives a long exact sequence,

$$\begin{array}{ccccccc} 0 & \longrightarrow & \mathcal{H}om_{\mathcal{O}_X}(\iota_* \mathcal{O}_C, \omega_X) & \longrightarrow & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X, \omega_X) & \xrightarrow{f} & \mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X(-D_C), \omega_X) \\ & & & & & & \downarrow \\ & & & & & & \mathcal{E}xt_{\mathcal{O}_X}^1(\iota_* \mathcal{O}_C, \omega_X) \longrightarrow \mathcal{E}xt_{\mathcal{O}_X}^1(\mathcal{O}_X, \omega_X) \longrightarrow \dots \end{array}$$

Since $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X, -)$ is the identity functor, we get $\mathcal{E}xt_{\mathcal{O}_X}^1(\mathcal{O}_X, -) = 0$. Furthermore, by duality, $\mathcal{H}om_{\mathcal{O}_X}(\iota_* \mathcal{O}_C, \omega_X) = 0$ since top cohomology of $\iota_* \mathcal{O}_C$ vanishes because ι is affine and \mathcal{O}_C has vanishing cohomology above degree one. Therefore, we find an exact sequence,

$$0 \longrightarrow \omega_X \xrightarrow{f} \mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X(-D_C), \omega_X) \longrightarrow \mathcal{E}xt_{\mathcal{O}_X}^1(\iota_* \mathcal{O}_C, \omega_X) \longrightarrow 0$$

However, X is Cohen-Macaulay and C is in codimension one so $\mathcal{E}xt_{\mathcal{O}_X}^1(\iota_* \mathcal{O}_C, \omega_X)$ computes the dualizing sheaf $\iota_* \omega_C$ [CITE THIS IN STACKS PROJECT].

If C is Cartier, then $\mathcal{O}_X(-D_C)$ is invertible so,

$$\mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X(-D_C), \omega_X) = \mathcal{O}_X(D_C) \otimes_{\mathcal{O}_X} \omega_X = \omega_X(D_C) = \mathcal{O}_X(D_C + K_X)$$

To show this in the non Cartier case, we need to make a diversion into reflexive sheaves. When X is a normal projective variety, the dualizing sheaf is reflexive giving a canonical divisor $\omega_X = \mathcal{O}_X(K_X)$. Furthermore, the following formula holds for reflexive sheaves on normal varieties (Theorem 8.35),

$$\mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X(-D), \mathcal{O}_X(E)) = \mathcal{O}_X(D + E)$$

Thus, we do get an exact sequence,

$$0 \longrightarrow \mathcal{O}_X(K_X) \xrightarrow{f} \mathcal{O}_X(D_C + K_C) \longrightarrow \iota_*\omega_C \longrightarrow 0$$

viewing f as a section of $\mathcal{O}_X(D_C)$, using that $D_C + \text{div}(f) = C$ is effective, gives $\mathcal{O}_X \xrightarrow{f} \mathcal{O}_X(D_C)$. Then, tensoring by $-\otimes_{\mathcal{O}_X} \omega_X$ and using $\mathcal{O}_X(D) \otimes_{\mathcal{O}_X} \mathcal{O}_X(E) \rightarrow \mathcal{O}_X(D + E)$ via $f \otimes g \mapsto fg$ gives the above map. \square

The previous theorem shows that Δ -nondegeneracy is sufficient for the closure of U_f to embed smoothly. However, it is not necessary since the condition requires that the curve does not pass through the codimension-two toric components. We will use the following remark to weaken our nondegeneracy condition on f . First, we prove an extension of Baker's theorem which applies without the nondegeneracy condition.

Theorem 4.2. For any Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$ such that U_f is a curve and $\Delta(f) = \Delta$,

$$g(U_f) \leq |\Delta^\circ \cap \mathbb{Z}^2|$$

with equality exactly when the scheme theoretic image of $U_f \hookrightarrow \mathbb{T}_\Delta$ is smooth.

Proof. See [Dok18, Section 2] and [?, Section 2]. Here, we will give a sketch of the proof. Let $N = |\Delta \cap \mathbb{Z}^2|$ and V be the number of vertices of Δ then the parameter space of Laurent polynomials $f \in k[x^{\pm 1}, y^{\pm 1}]$ such that $\Delta(f) = \Delta$ is exactly $L = \mathbb{A}_k^{N-V} \times_k \mathbb{G}_{m,k}^V$ where we associate a k -rational point $(a_{ij}) \in \mathbb{A}_k^{N-V} \times_k \mathbb{G}_{m,k}^V$ to the Laurent polynomial,

$$f = \sum_{(i,j) \in \Delta} a_{ij} x^i y^j$$

Note that $\Delta(f) = \Delta$ since the coefficients a_{ij} corresponding to vertices $(i, j) \in \Delta$ are nonzero. Now, consider the closed subscheme,

$$V \subset \mathbb{G}_{m,k}^2 \times_k \mathbb{A}_k^{N-V} \times_k \mathbb{G}_{m,k}^V = \text{Spec}(k[x^{\pm 1}, y^{\pm 1}]) \times \text{Spec}(k[a_{ij}, a_{i,j}^{-1} | (i,j) \in V])$$

defined by the vanishing,

$$V = V \left(\sum_{(i,j) \in \Delta} a_{ij} x^i y^j \right)$$

Then the projection gives a family $\pi : V \rightarrow L$ of torus curves parameterized by the coefficients of their Laurent polynomials. Now, we complete V under the open immersion $\mathbb{G}_{m,k}^2 \times_k L \hookrightarrow \mathbb{T}_\Delta \times_k L$ to get a closed immersion $\mathcal{C} \hookrightarrow \mathbb{T}_\Delta \times_k L$ whose fiber over f gives the Δ -toric completion of U_f ,

$$\begin{array}{ccccc} V & \hookrightarrow & \mathcal{C} & \hookrightarrow & \mathbb{T}_\Delta \times_k L \\ & & \searrow & & \downarrow \pi \\ & & & & L \end{array}$$

By [CDV06, Section 2, Prop. 1], the locus of L corresponding to Δ -nondegenerate f contains a Zariski dense open. Therefore, the general fiber \mathcal{C}_{f_0} above $f_0 \in k[x^{\pm 1}, y^{\pm 1}]$ corresponds to C_0^Δ , the completion of $C_0 = U_{f_0}$, which is smooth proper curve with genus and thus arithmetic genus,

$$g_a(U_f^\Delta) = g(U_f^\Delta) = |\Delta^\circ \cap \mathbb{Z}^2|$$

by the version of Baker's theorem proven above. I claim the family $\mathcal{C} \rightarrow L$ is flat. First, the projection $X = \mathbb{T}_\Delta \times_k L \rightarrow L$ is flat and consider $\mathcal{O}_{L, \pi(x)} \rightarrow \mathcal{O}_{X, x}$ then we take the germ $f \in \mathcal{O}_{X, x}$ when $x \in \mathbb{G}_{m, k}^2 \times_k L$ given by,

$$f = \sum_{(i, j) \in \Delta} a_{ij} x^i y^j$$

Then $f \in \mathcal{O}_{X, x} / \mathfrak{m}_{\pi(x)} \mathcal{O}_{X, x} = \mathcal{O}_{X, x} \otimes_{\mathcal{O}_{L, \pi(x)}} \kappa(\pi(x))$ is a zero divisor exactly when not all $a_{ij} \in \mathfrak{m}_{\pi(x)}$ since x, y are invertible on $\mathbb{G}_{m, k}^2$. However, since the Newton polygon is held fixed on L we never have the vanishing of all a_{ij} . Then applying [Tag 046Z] we see that $\mathcal{O}_{L, \pi(x)} \rightarrow \mathcal{O}_{X, x} / (f)$ is flat and thus $\mathcal{C} \rightarrow L$ is flat. (THIS IS NOT QUITE RIGHT) Furthermore, $\mathcal{C} \hookrightarrow \mathbb{T}_\Delta \times_k L \hookrightarrow \mathbb{P}_k^n \times_k L$ is a closed subscheme which implies [Har77, Thm. III.9.10] that the arithmetic genus of the fibers is constant. Thus, for any $f \in k[x^{\pm 1}, y^{\pm 1}]$ such that U_f is a smooth curve, then its toric completion U_f^Δ has arithmetic genus,

$$g_a(U_f^\Delta) = g_a(C_0^\Delta) = |\Delta^\circ \cap \mathbb{Z}^2|$$

We use the following lemmas to conclude that,

$$g(U_f) = g(U_f^\Delta) \leq g_a(U_f^\Delta) = |\Delta^\circ \cap \mathbb{Z}^2|$$

which equality exactly when U_f^Δ is smooth. Furthermore, since $\mathcal{C} \rightarrow L$ is a proper flat family, by Zariski connectedness the fibers are connected so we see that *any* U_f^Δ with $\Delta(f) = \Delta$ is connected (even when U_f is not a curve i.e. not connected). \square

Remark. We have shown that U_f^Δ is connected whenever $\Delta(f) = \Delta$ but the affine curve U_f certainly may not be. For example, consider $f_1 = (x + y - 1)(x + y + 1)$ and $f_2 = x^2 + y^2 - 1$ then $\Delta(f_1) = \Delta(f_2) = 2\Sigma$ where Σ is the unit isosceles right triangle. However,

$$U_{f_1} = \text{Spec}(k[x^{\pm 1}, y^{\pm 1}]/(f_1)) = \text{Spec}(k[k[x^{\pm 1}, y^{\pm 1}]/(x + y - 1)] \times_k \text{Spec}(k[k[x^{\pm 1}, y^{\pm 1}]/(x + y + 1)])$$

which is the union of two parallel lines in $\mathbb{G}_{m, k}^2$ (which do not intersect in the torus) while,

$$U_{f_2} = \text{Spec}(k[x^{\pm 1}, y^{\pm 1}]/(f_2)) = \text{Spec}(k[x^{\pm 1}, y^{\pm 1}]/(x^2 + y^2 - 1))$$

is irreducible and thus connected. However, in the toric completion $U_{f_1}^\Delta$ (which lies in $\mathbb{T}_{2\Sigma} = \mathbb{P}_k^2$), these two parallel lines do in fact intersect so both $U_{f_1}^\Delta$ and $U_{f_2}^\Delta$ are connected.

Definition 4.25. We say that $f \in k[x^{\pm 1}, y^{\pm 1}]$ is *weakly Δ -nondegenerate* when the following hold,

- (a). $\Delta(f) \subset \Delta$
- (b). for each face $\tau \subset \Delta$ we have $\tau \cap \Delta(f) \neq \emptyset$
- (c). the affine curve U_f is smooth with genus $g(U_f) = |\Delta^{(1)} \cap \mathbb{Z}^2|$.

Weakly Δ -nondegenerate Laurent polynomials $f \in k[x^{\pm 1}, y^{\pm 1}]$ do indeed define affine curves U_f with an embedding $U_f \hookrightarrow \mathbb{T}_\Delta$ such that the completion C_0^Δ is smooth and satisfies the numerical genus condition of Baker. However, such curves will not, in general, be Cartier divisors on \mathbb{T}_Δ since they may pass through the singular locus where \mathbb{T}_Σ is not locally factorial.

Lemma 4.26. In the third condition definition of weakly Δ -nondegenerate Laurent polynomials, it is equivalent to assume that the scheme theoretic image of $U_f \hookrightarrow \mathbb{T}_\Delta$ is smooth.

Proof. When U_f^Δ is smooth then we have $g(U_f^\Delta) = g_a(U_f^\Delta) = |\Delta^\circ \cap \mathbb{Z}^2|$. Conversely, we have that $\tilde{\Delta} = \Delta(f) \subset \Delta$ (from the definition that f is weakly Δ -nondegenerate) and we assume $g(U_f) = |\Delta^\circ \cap \mathbb{Z}^2|$. From Baker's bound,

$$g(U_f^\Delta) = g(U_f) \leq |\tilde{\Delta}^\circ \cap \mathbb{Z}^2| \leq |\tilde{\Delta}^\circ \cap \mathbb{Z}^2|$$

Thus, from the assumption these are equalities so,

$$g(U_f^\Delta) = |\tilde{\Delta}^\circ \cap \mathbb{Z}^2|$$

and thus U_f^Δ is smooth by the above result. \square

4.5 The Inverse Problem

Up until now we have discussed the situation of specifying a curve by a fixed Laurent polynomial and attempting to describe the unique smooth complete curve in its birationality class via a toric completion. However, here we consider the inverse problem: given a (smooth complete) curve C , we might ask when one can find a dense open set $U \subset C$ with a closed embedding $U \hookrightarrow \mathbb{G}_{m,k}^2$ such that the resultant Laurent polynomial describing the torus curve U satisfies the nondegeneracy conditions we have discussed earlier.

Definition 4.27. Given a convex lattice polygon Δ , we say that a curve k over k is (weakly) Δ -nondegenerate over k if it is birational over k to a curve $U \subset \mathbb{T}^2$ such that $U = V(f)$ for some (weakly) Δ -nondegenerate Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$. In the case that C is weakly Δ -nondegenerate, we will alternatively say that C is Δ -toric to emphasize that C embeds into the toric surface \mathbb{T}_Δ . Furthermore, we say that C is geometrically (weakly) Δ -nondegenerate if $C \times_k \bar{k}$ is (weakly) Δ -nondegenerate over \bar{k} .

First we note that using the terms weakly Δ -nondegenerate and Δ -toric interchangeably will introduce no confusion because of the following result which shows that any curve which may be embedded in a toric surface is weakly nondegenerate.

Proposition 4.28. Let $C \hookrightarrow \mathbb{T}_\Delta$ be an embedding of a non-rational smooth curve into a toric surface. Then C is weakly $\tilde{\Delta}_C$ -nondegenerate where $\tilde{\Delta}_C = \text{Conv}(P_C \cap \mathbb{Z}^2)$.

Proof. Since C is nonrational, it cannot lie in the toric divisor $D_{\mathbb{T}}$ which is a union of toric varieties which are rational because every irreducible subvariety of the toric divisor is rational. Therefore it must intersect the torus, $C \cap \mathbb{T}^2 \neq \emptyset$ so $C \cap \mathbb{T}^2$ gives some curve $U_f \subset \mathbb{G}_{m,k}^2$ defined by an irreducible Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$. Then the linearly equivalent divisor $D_C = C - \text{div}(f)$ is torus-invariant since it is supported on $D_{\mathbb{T}}$ because $C|_{\mathbb{T}^2} = \text{div}(f)|_{\mathbb{T}^2}$ on the torus.

Now we consider the rational polytope P_{D_C} of the torus-invariant Weil divisor D_C (note D_C may not be Cartier and P_{D_C} may not be a lattice polytope). However, $D_C + \text{div}(f) = C$ is effective so $f \in H^0(\mathbb{T}_\Delta, \mathcal{O}_{\mathbb{T}_\Delta}(D_C))$ which implies that $\Delta(f) \subset P_{D_C}$ because there is a decomposition,

$$H^0(\mathbb{T}_\Delta, \mathcal{O}_{\mathbb{T}_\Delta}(D_C)) = \bigoplus_{(i,j) \in P_{D_C} \cap \mathbb{Z}^2} k \cdot x^i y^j$$

Figure 2: The polygons Δ in black and $\Delta(f)$ in red for $f = x^5 + y^2 + x^2y^3 + 1$ in example of Proposition 4.29.

so the support of f must be contained in $P_{D_C} \cap \mathbb{Z}^2$. Even better, this shows that,

$$\Delta(f) \subset \text{Conv}(P_{D_C} \cap \mathbb{Z}^2) = \tilde{\Delta}_C \subset P_{D_C}$$

Now, since C is smooth, by our refinement of Baker's bound (Theorem 4.2) we have,

$$g(C) \leq |\Delta(f)^{(1)} \cap \mathbb{Z}^2| \leq |\tilde{\Delta}_C^{(1)} \cap \mathbb{Z}^2|$$

As in the proof of Baker's theorem, we want to apply the exact sequence of Theorem 4.24,

$$0 \longrightarrow \mathcal{O}_X(K_X) \longrightarrow \mathcal{O}_X(D_C + K_X) \longrightarrow \mathcal{O}_C(K_C) \longrightarrow 0$$

which gives an isomorphism $H^0(X, \mathcal{O}_X(D_C + K_X)) \xrightarrow{\sim} H^0(C, \omega_C)$. \square

Remark. Notice, in the proof of Theorem 4.2, we use the fact (proven in [CDV06, Section 2, Prop. 1]) that the generic Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$ with fixed Newton polygon Δ is Δ -nondegenerate. However, we have shown that a very general curve cannot lie on any toric surface and thus cannot be Δ -toric let alone Δ -nondegenerate. How can these facts be consistent? It must be that under the equivalence relation,

$$f \sim f' \iff U_f \xrightarrow{\sim} U_{f'} \iff \text{Frac}(k[x^{\pm 1}, y^{\pm 1}]/(f)) \cong \text{Frac}(k[x^{\pm 1}, y^{\pm 1}]/(f'))$$

a general equation does not define a class corresponding to a general curve. In fact, the general Laurent polynomial $f \in k[x^{\pm 1}, y^{\pm 1}]$ with fixed $\Delta = \Delta(f)$ lies in the subspace of the moduli space corresponding to Δ -nondegenerate curves.

Since the two notions are very similar, we naturally ask if weak and strong Δ -regularity are equivalent properties. Restricting ourselves to a fixed lattice polygon Δ , Castryck has provided a negative answer to this question by constructing a weakly Δ -nondegenerate curve which has no embedding into \mathbb{T}_Δ which intersects the toric divisor transversally. In particular, he showed that:

Proposition 4.29. There exists a lattice polygon Δ and a curve C such that C is weakly Δ -nondegenerate but not Δ -nondegenerate. Specifically, consider the Laurent polynomial,

$$f = x^5 + y^2 + x^2y^3 + 1 \in k[x^{\pm 1}, y^{\pm 1}]$$

and the lattice polygon $\Delta = \text{Conv}(\{(0, 0), (5, 0), (2, 3), (0, 3)\})$.

Figure 3: Rays of the normal fans of Δ (black) and $\Delta(f)$ (red). Notice that the normal fan of $\Delta(f)$ gives a toric blowup of the fan of Δ .

Proof. See [CC16, Lemma 4.4]. The proof uses the theory of trigonal curves and the canonical embedding using that $\Delta^{(1)}$ and Δ have the same normal fan for this particular choice of polygon. (GIVE MORE DETAILS?). We can understand intuitively why this example works. The toric variety \mathbb{T}_Δ is a Hirzebruch surface and the curve $C_0^\Delta \hookrightarrow \mathbb{T}_\Delta$ is tangent to the torus divisor at the component defined by the vertex $V = (0, 3)$ in the polygon Δ showing that this curve is not Δ -nondegenerate. Furthermore, the Hirzebruch surface has a single parameter family of automorphism which translates the tangency point along the toric divisor which is why no equation for C_0 can be Δ -nondegenerate. Notice that $\Delta(f) \subsetneq \Delta$ and the normal fan of $\Delta(f)$ contains an additional ray. Therefore, $\mathbb{T}_{\Delta(f)}$ corresponds to the toric blowup of the tangency point which turns the tangency into a transverse intersection which explains why f is $\Delta(f)$ -nondegenerate which is easily verified by a computation of the derivatives. \square

Notice that the curve Castryck constructs is actually nondegenerate (with respect to its own Newton polygon) and is only not nondegenerate for a specific choice of Δ for which it is weakly Δ -nondegenerate. We suspect that there exist examples of curves which are Δ -toric for some Δ but never Δ -nondegenerate *for any* Δ . However, as of now, such examples remain illusory. Although we have shown that a very general curve cannot be Δ -toric (let alone Δ -nondegenerate) for any Δ , low genus curves turn out to be well-behaved with respect to toric regularity. In particular, Castryck showed that all curves of genus 4 or less admit a nondegenerate affine equation.

Theorem 4.3 (Cas17, Thm. 10). Every curve C/k of genus $g(C) \leq 4$ is Δ -nondegenerate for exactly one of a fixed finite list of lattice polygons Δ ,

5 Models of Curves

Remark. We will be in the situation where R is a DVR and $K = \text{Frac}(R)$ its fraction field. Then let $\mathfrak{m} \subset R$ be the maximal ideal and $\kappa = R/\mathfrak{m}$ the residue field. We may distinguish the *geometric* case in the special fiber when κ is algebraically closed and otherwise when κ admits algebraic extensions.

Definition 5.1. Let X be a scheme of finite type over K . A model \mathcal{X} of X over R is a scheme over R such that $\mathcal{X} \rightarrow \text{Spec}(R)$ is flat and finite type given an isomorphism $X \xrightarrow{\sim} \mathcal{X}_K$ where $\mathcal{X}_K = \mathcal{X} \times_{\text{Spec}(R)} \text{Spec}(K)$ is the generic fiber. A morphism $f : \mathcal{X} \rightarrow \mathcal{X}'$ of models of X is an R -morphisms of schemes inducing an isomorphism $f : \mathcal{X}_K \rightarrow \mathcal{X}'_K$ compatible with the isomorphisms $X \xrightarrow{\sim} \mathcal{X}_K$ and $X \xrightarrow{\sim} \mathcal{X}'_K$.

Remark. We require models to be flat over R so that the generic fiber X_K and the special fiber $X_\kappa = X \times_{\text{Spec}(R)} \text{Spec}(\kappa)$ form a flat family over $\text{Spec}(R)$ such that numerical invariants are preserved under the degeneration from the general to the special fiber.

Proposition 5.2. Let C be a smooth projective curve over K and X a model of C over R . Then X admits a resolution of singularities $\tilde{X} \rightarrow \text{Spec}(R)$ and any such resolution is a model of C .

Proof. This result follows from the general criteria for resolution of surfaces due to Lipman [Lip78]. See Stacks Tag 0C2U for details. \square

5.1 Minimal Models

Definition 5.3. Let C be a smooth projective curve over K with $H^0(C, \mathcal{O}_C) = K$. A *minimal model* is a regular, proper model X of C such that X does not contain an exceptional curve of the first kind.

Definition 5.4. We call the following an *exceptional curve of the first kind*:

Let X be a Noetherian scheme. Let $E \subset X$ be a closed subscheme with the following properties,

- (a). E is an effective Cartier divisor on X ,
- (b). there exists a field k and an isomorphism $\mathbb{P}_k^1 \rightarrow E$,
- (c). the normal sheaf $\mathcal{N}_{E/X}$ pulls back to $\mathcal{O}_{\mathbb{P}_k^1}(-1)$.

Remark. We can reinterpret the condition of the normal bundle $\mathcal{N}_{E/X}$ that it pullback to $\mathcal{O}_{\mathbb{P}_k^1}(-1)$ in terms of intersection theory. Recall that given Cartier divisors $C_1, C_2 \subset X$ we can define the intersection number $C_1 \cdot C_2 = \chi(\mathcal{O}_X(C_1)|_{C_2}) - \chi(\mathcal{O}_{C_2})$. In more generality, there is an intersection product on the Chow groups $\text{CH}^i(X) \times \text{CH}^j(X) \rightarrow \text{CH}^{i+j}(X)$ giving $\text{CH}^\bullet(X)$ a ring structure defining the Chow ring. In our case the intersection number is the map,

$$\text{CH}^1(X) \times \text{CH}^1(X) \rightarrow \text{CH}^2(X) \xrightarrow{\deg} \mathbb{Z}$$

where the degree map $\deg : \text{CH}^2(X) \rightarrow \mathbb{Z}$ exists on a proper surface X since relations in $\text{CH}^2(X)$ are given by divisors of functions on closed curves in X which have zero degree since they are proper. This agrees with the intersection number $C_1 \cdot C_2 = \chi(\mathcal{O}_X(C_1)|_{C_2})$. Now, consider the self-intersection $C \cdot C = \chi(\mathcal{O}_X(C)|_C)$. However, since $\mathcal{O}_X(C)$ is the dual of the sheaf of ideals defining $\iota : C \hookrightarrow X$ then $\mathcal{O}_X(C)|_C = (\iota^* \mathcal{I})^\vee = \mathcal{N}_{C/X}$ is the normal bundle. Therefore, $C \cdot C = \chi(\mathcal{N}_{C/X}) - \chi(\mathcal{O}_C)$ for

a Cartier divisor $C \hookrightarrow X$. In the case that C is a smooth curve on a projective surface, we have using Riemann-Roch,

$$C \cdot C = \chi(\mathcal{N}_{C/X}) - \chi(\mathcal{O}_C) = \deg(\mathcal{N}_{C/X})$$

When E is an exceptional curve with an isomorphism $f : \mathbb{P}_k^1 \xrightarrow{\sim} E$ such that $f^*\mathcal{N}_{E/X} = \mathcal{O}_{\mathbb{P}_k^1}(-d)$ then $E \cdot E = \deg(\mathcal{N}_{E/X}) = \deg \mathcal{O}_{\mathbb{P}_k^1}(-d) = -d$. We say in this case that E is a $-d$ curve.

Remark. For our purposes, the important fact about exceptional curves of the first kind is that they allow blowing down while retaining regularity of the surface which explains why our notion of minimality of a model excludes having exceptional curves of the first kind.

5.2 Contracting Exceptional Curves (WIP)

Definition 5.5. Let $f : X \rightarrow Y$ be a morphism of schemes and $D \subset X$ an effective Cartier divisor. Then $f : X \rightarrow Y$ is a contraction of D if f is proper such that $f(E) = \{y\}$ for some closed point $y \in Y$ where $\mathcal{O}_{Y,y}$ is regular and $\dim \mathcal{O}_{Y,y} = 2$ and such that $f : X \rightarrow Y$ is the blowup of Y at y .

Lemma 5.6 (0C5J). Let X be a Noetherian scheme. Let $E \subset X$ be an exceptional curve of the first kind. If a contraction $f : X \rightarrow X'$ of E exists, then it satisfies the following universal property: for every morphism $\varphi : X \rightarrow Y$ such that $\varphi(E)$ is a point, then φ factors uniquely through $f : X \rightarrow X'$,

$$\begin{array}{ccccc} E & \hookrightarrow & X & \xrightarrow{\varphi} & Y \\ \downarrow f & & \downarrow f & \nearrow \varphi & \\ \mathrm{Spec}(\kappa(x')) & \hookrightarrow & X' & & \end{array}$$

Corollary 5.7. If it exists, any contraction of $E \subset X$ is unique up to unique isomorphism.

Proof. Uniqueness following directly from the universal property. \square

Proposition 5.8 (Tag 0C2L). Let X be Noetherian and $E \subset X$ an exceptional curve of the first kind. Suppose there is a morphism $f : X \rightarrow Y$ such that,

- (a). Y is Noetherian
- (b). f is proper
- (c). $f(E) = \{y\}$ for a closed point $y \in Y$
- (d). f is quasi-finite at each point of E

then there exists a contraction of E .

5.3 Existence and Uniqueness of Minimal Models

Lemma 5.9. Let C be a smooth projective curve over K with $H^0(C, \mathcal{O}_C) = K$. If X is a regular proper model for C , then there exists a sequence of morphisms,

$$X = X_m \longrightarrow X_{m-1} \longrightarrow \cdots \longrightarrow X_1 \longrightarrow X_0$$

of proper regular models of C , such that each morphism is a contraction of an exceptional curve of the first kind, and such that X_0 is a minimal model.

Proposition 5.10. Let C be a smooth projective curve over K with $H^0(C, \mathcal{O}_C) = K$. A minimal model X of C over R exists.

Proof. Choose a closed immersion $C \rightarrow \mathbb{P}_K^n$ and let X be the scheme-theoretic image of the immersion, $C \rightarrow \mathbb{P}_K^n \rightarrow \mathbb{P}_R^n$. Then by some lemmas $X \rightarrow \operatorname{Spec}(R)$ is a projective model of C and there exists a resolution of singularities $X' \rightarrow X$ and X' is a model for C (Lemma 5.2). Then $X' \rightarrow \operatorname{Spec}(R)$ is proper as a composition of proper morphisms. Then we use the previous result to obtain a minimal model by blowing down. \square

Proposition 5.11 (Tag 0C6B). Let C be a smooth projective curve over K with $H^0(C, \mathcal{O}_C) = K$ and positive genus. The minimal model X of C over R is unique.

Proposition 5.12 (Tag 0C9Z). Let C be a smooth projective curve over K with $H^0(C, \mathcal{O}_C) = K$ and positive genus. Let X be the minimal model for C over R . Let Y be a regular proper model for C . Then there is a unique morphism of model $Y \rightarrow X$ which is a sequence of contractions of exceptional curves of the first kind.

Remark. If the curve C has genus zero. Then minimal models are generically non-unique. An example is given in Tag 0CA0.

Remark. The minimal model (proper, regular, no exceptional curves of the first kind, then minimal with respect to these conditions) does not necessarily agree with the minimal regular normal crossings model (proper, regular, strict normal crossings divisors in the special fiber, minimal with respect to these conditions). This is because the minimal model may require blowing up to get strict normal crossings. However, the minimal regular normal crossings model gives the minimal model via blowing down.

5.4 Normal Crossings Models (WIP)

Our discussion thus far has considered regular models in some generality. However, the special fiber of a regular model may have fairly nasty singularities in general. Therefore, we introduce the notion of a regular normal crossings divisor in order to control how bad the singularities can be. Intuitively, a regular normal crossings divisor has singularities only from smooth irreducible components intersecting transversally.

Definition 5.13. Let X be a locally Noetherian scheme. A *strict normal crossings divisor* on X is an effective Cartier divisor $D \subset X$ such that for each $p \in D$ the local ring $\mathcal{O}_{X,p}$ is regular and there exists a regular system of parameters $x_1, \dots, x_d \in \mathfrak{m}_p$ and $1 \leq r \leq d$ such that D is cut out by $x_1 \cdots x_r \in \mathcal{O}_{X,p}$.

Example 5.14. Consider the closed subscheme of \mathbb{A}_k^2 ,

$$X = \operatorname{Spec}(k[x, y]/(xy))$$

Then consider the point $p = (x, y)$ so we need to consider the ring,

$$\mathcal{O}_{X,p} = (k[x, y]/(xy))_{(x,y)}$$

with maximal ideal,

$$\mathfrak{m}_p = (x, y)$$

I claim that this is a regular system of parameters and

$$\mathfrak{m}_p/\mathfrak{m}_p^2 = kx \oplus ky$$

However, $\dim \mathcal{O}_{X,p} = 1$ since we have the maximal chain of primes $(y) \subset (x, y)$ so $\mathcal{O}_{X,p}$ is not regular. However, X is a strict normal crossings divisor of \mathbb{A}_k^2 since X is cut out by xy .

Example 5.15. Consider the closed subscheme of \mathbb{A}_k^2 ,

$$X = \operatorname{Spec} (k[x, y]/(y(x^2 - y)))$$

Then consider the point $p = (x, y)$ so we need to consider the ring,

$$\mathcal{O}_{X,p} = (k[x, y]/(y(x^2 - y)))_{(x,y)}$$

with maximal ideal,

$$\mathfrak{m}_p = (x, y)$$

I claim that this is a regular system of parameters and

$$\mathfrak{m}_p/\mathfrak{m}_p^2 = kx \oplus ky$$

However, $\dim \mathcal{O}_{X,p} = 1$ since we have the maximal chain of primes $(y) \subset (x, y)$ so $\mathcal{O}_{X,p}$ is not regular. Furthermore, X is a strict normal crossings divisor of \mathbb{A}_k^2 is not cut out by the products of the regular parameters.

Definition 5.16. Let X be a locally Noetherian scheme. A *normal crossings divisor* on X is an effective Cartier divisor $D \subset X$ such that for each $p \in D$ there is an étale map $f : U \rightarrow X$ hitting p such that $f^{-1}(D)$ is strict normal crossings.

Now we define our notion of a regular normal crossings model.

Definition 5.17. A regular normal crossings model $\mathcal{X} \rightarrow \operatorname{Spec}(R)$ of $X \rightarrow \operatorname{Spec}(K)$ is a regular model such that X_κ is a normal crossings divisor.

Remark. Note that $\operatorname{Spec}(\kappa) \hookrightarrow \operatorname{Spec}(R)$ is a Cartier divisor so the special fiber $X_\kappa \hookrightarrow X$ is a Cartier divisor via the base change.

QUESTION 5.18. It is correct to say that a minimal regular normal crossings model is one with no -2 -curves?

Theorem 5.19. Let C be a curve over K with $H^0(C, \mathcal{O}_C) = K$ with positive genus. Then C admits a unique minimal regular normal crossings model over R .

Proof. [Rom13] possible reference. (FIND REFERENCES) □

5.5 Structure of the Special Fiber (WIP)

Definition 5.20. Let C be a smooth projective curve over K with $H^0(C, \mathcal{O}_C) = K$ and X a regular proper model of C . Let C_1, \dots, C_n be the irreducible components of the special fiber X_κ . Then we write,

$$X_\kappa = \sum_i m_i C_i$$

where m_i is the multiplicity of C_i .

Lemma 5.21 (Tag 01WS). Let X be a regular model of a smooth curve C over K . Then,

- (a). the special fiber X_κ is an effective Cartier divisor on X ,
- (b). each irreducible component C_i of X_κ is an effective Cartier divisor on X ,
- (c). as Cartier divisors,

$$X_\kappa = \sum_i m_i C_i$$

where m_i is the multiplicity of C_i in X_κ ,

- (d). $\mathcal{O}_X(X_\kappa) \cong \mathcal{O}_X$.

Proposition 5.22. Let X be a regular proper model of C over R . Then genus g_C of the curve C may be computed on the special fiber X_κ as follows,

$$g_C = 1 + \sum_{i=1}^n m_i \left([\kappa(C_i) : \kappa](g_{C_i} - 1) - \frac{1}{2}(C_i \cdot C_i) \right)$$

where $\kappa(C_i) = H^0(C_i, \mathcal{O}_{C_i})$ and $g_{C_i} = \dim_{\kappa(C_i)} H^1(C_i, \mathcal{O}_{C_i})$ is the genus.

6 Toric Construction of Models

In this section we discuss the results of [Dok18] which gives a method of explicitly constructing a regular normal crossings model of a curve and explicitly describing its special fiber using the preceding methods characterizing curves on toric surfaces.

Remark. In [Dok18], Dokchitser often uses “curve” to refer to an integral separated *geometrically connected* scheme of finite type over a field. To mitigate any confusion, we render any results quoted from his work with “curve” replaced by “geometrically connected curve” when necessary.

6.1 Notations and Definitions

We work in the case of a discretely definition valued field K with valuation $\nu : K^\times \rightarrow \mathbb{Z}$, valuation ring R , uniformizer ϖ , and residue field κ . Given a smooth projective geometrically connected curve over K our goal will be to construct a regular normal crossings model over R . First we need to fix some notation.

Definition 6.1. Given a Laurent polynomial $f \in K[x^{\pm 1}, y^{\pm 1}]$ recall the Newton polygon is,

$$\Delta(f) = \text{Conv}(\{(i, j) \in \mathbb{Z}^2 \mid a_{ij} \neq 0\}) \subset \mathbb{R}^2$$

We will assume throughout that $\text{vol}(\Delta) > 0$. Now we refine the Newton polygon with respect to the valuation $\nu : K^\times \rightarrow \mathbb{Z}$,

$$\Delta_\nu(f) = \text{LowerConvHull}(\{(i, j, v(a_{ij})) \mid (i, j) \in \Delta(f) \cap \mathbb{Z}^2\}) \subset \mathbb{R}^2 \times \mathbb{R}$$

The projection $\pi : \Delta_\nu \rightarrow \Delta$ is a homomorphism. Thus, for each point $P \in \Delta$ there is a unique point $(P, \nu(P)) \in \Delta_\nu$ which defines a piece-wise affine function $v : \Delta \rightarrow \mathbb{R}$ extending the valuation.

The bijection $\pi : \Delta_\nu \rightarrow \Delta$ pushes the polyhedral structure on Δ_ν onto Δ . Because Δ_ν is the lower convex hull of finitely many points in $\mathbb{R}^2 \times \mathbb{R}$ it decomposes into faces of dimension 0, 1, 2. Under the projection $\pi : \Delta_\nu \rightarrow \Delta$ the v -vertices P of Δ are the images of the 0-faces, the v -edges L are the images of the 1-faces, the v -faces F are the images of the 2-faces. These define a polygonal partition of Δ .

Definition 6.2. For each edge L and face F there is an associated integer δ_λ (with $\lambda = L$ or F), the *denominator*, defined as smallest positive m such that $\nu(P) \in \frac{1}{m}\mathbb{Z}$ for each $P \in \lambda \cap \mathbb{Z}^2$.

Remark. We now consider how to restrict a polynomial with respect to the ν -partition to form a Laurent polynomial supported on the faces and vertices. First, following the Notation of [Dok18] we define how to restrict the polynomial to some subset of a lattice.

Definition 6.3 (Restriction). Let $S \subset \mathbb{Z}^n$ be a nonempty subset of a lattice and take Λ to be the smallest affine lattice $S \subset \Lambda \subset \mathbb{Z}^n$ containing S . Let Λ have rank r and choose an isomorphism $\phi : \mathbb{Z}^r \rightarrow \Lambda$. Then for a Laurent polynomial $g \in K[\mathbf{x}^{\pm 1}]$ we define the restriction $g|_S \in K[\mathbf{y}^{\pm 1}]$,

$$g|_S = \sum_{\mathbf{i} \in \phi^{-1}(S)} c_{\phi(\mathbf{i})} \mathbf{y}^{\mathbf{i}} \in K[\mathbf{y}^{\pm 1}] \quad \text{for} \quad g = \sum_{\mathbf{i} \in \mathbb{Z}^n} c_{\mathbf{i}} \mathbf{x}^{\mathbf{i}}$$

Note that different choices of an isomorphism $\Lambda \rightarrow \mathbb{Z}^r$ are related by an automorphism in $\text{GL}_r(\mathbb{Z})$ acting on the variables \mathbf{y} .

Remark. The notational complexity of the above definition derives from making the polynomial $g|_S$ an element of a standard Laurent polynomial ring $k[\mathbf{y}^{\pm 1}]$. We can simplify the above notation using our previous abstract notation used for the toric constructions. Given a lattice M and a Laurent polynomial $g \in K[M]$ and a subset $S \subset M$ we define the restriction,

$$g|_S = \sum_{m \in S} c_m \chi^m \in K[\langle S \rangle] \quad \text{where} \quad g = \sum_{m \in M} c_m \chi^m$$

where $\langle S \rangle$ is the sublattice of M generated by S . The above definition is recovered choosing some isomorphism $\phi : \langle S \rangle \rightarrow \mathbb{Z}^r$ giving an isomorphism $K[\langle S \rangle] \cong K[\mathbf{y}]$.

Definition 6.4 (Reduction). For a Laurent polynomial $h \in K[x^{\pm 1}, y^{\pm 1}]$, there exist integers, $c, m, n \in \mathbb{Z}$ such that $\tilde{h}(x, y) = \varpi^c h(\varpi^m x, \varpi^n y)$ has coefficients in R and $\tilde{h} \bmod \varpi \in \kappa[x, y]$ has the same Newton polygon as h . Then we say that $\bar{h} = \tilde{h} \bmod \varpi$ is *reduction* of h .

Example 6.5. (DO THIS!!!!!!)

Definition 6.6. In particular for λ an edge L or face F we define the restriction $f|_\lambda = f|_S$ for the set, $S = \{P \in \lambda \cap \mathbb{Z}^2 \mid \nu(P) \in \mathbb{Z}\}$. Note, S contains the vertices of L or F .

Remark. Reduction gives, for each edge L and face F , polynomials $\overline{f|_L} \in \kappa[t]$ and $\overline{f|_F} \in \kappa[x, y]$. This gives affine curves over κ on each edge and face which we complete in a toric compactification as follows.

Definition 6.7 (Components). We define the following schemes over κ :

- (a). $X_L = V(\overline{f|_L}) \subset \mathbb{G}_{m, \kappa}$
- (b). $X_F = V(\overline{f|_F}) \subset \mathbb{G}_{m, \kappa}^2$
- (c). $\overline{X}_F = X_F^\Delta$ is the completion of X_F with respect to its Newton polygon F i.e. the closure of the immersion $X_F \hookrightarrow \mathbb{G}_{m, \kappa}^2 \hookrightarrow \mathbb{T}_F$. By Theorem 4.2, \overline{X}_F is connected and, in fact, the Theorem applies for any finite extension $\kappa' \supset \kappa$ showing that \overline{X}_F is geometrically connected.

Example 6.8. (DO EXAMPLE!!!!!!)

Definition 6.9. We say that $f \in k[x^{\pm 1}, y^{\pm 1}]$ is *strictly Δ_ν -regular* if all X_F and X_L are smooth over κ .

Remark. The condition that all X_L are smooth implies that f is nondegenerate with respect to its Newton polygon since it implies that f restricted to each edge is smooth.

Definition 6.10. A Laurent polynomial $f \in K[x^{\pm 1}, y^{\pm 1}]$ is *Δ_ν -regular* if each X_F is smooth and for the interior edges L and edges $L \subset \partial F$ with $\delta_L \neq \delta_F$ we require X_L is smooth and otherwise we require \overline{X}_F is *outer-regular* i.e. smooth at the points corresponding to L via the bijection of $\text{Gal}(\kappa^{\text{sep}}/\kappa)$ -sets,

$$\overline{X}_F(\bar{\kappa}) \setminus X_K(\bar{\kappa}) \longleftrightarrow \coprod_{L \supset \partial F} X_L(\bar{\kappa})$$

which derives from Baker's theorem. Since \overline{X}_F is a toric compactification of X_F , the additional points correspond to the vanishing of the equation along the toric divisors which correspond to edges $L \subset \partial F$ so smoothness of \overline{X}_F is ensured by outer-regularity.

Remark. As with toric regularity, we have defined the notion of Δ_ν -regular with respect to a given Laurent polynomial i.e. to a given affine model C_0 of a curve. As before, we extend this definition to an arbitrary curve in the obvious way.

Definition 6.11. A curve C over K is (strictly) Δ_ν -regular if C is birationally equivalent to some affine $U_f \subset \mathbb{G}_{m,K}^2$ for some (strictly) Δ_ν -regular Laurent polynomial $f \in K[x^{\pm 1}, y^{\pm 1}]$.

Remark. We need one more notion in order to describe the model of C which is a combinatorial connectivity between two adjacent faces F_1, F_2 sharing an edge L .

Definition 6.12 (Slopes). Edges are either *inner/interior* meaning they form the boundary between two ν -faces F_1 and F_2 or *outer/exterior* on the boundary of Δ . For an edge L there is a unique affine function $L_{(F_1)}^* : \mathbb{Z}^2 \rightarrow \mathbb{Z}$ with $L_{(F_1)}^*|_L = 0$ and $L_{(F_1)}^*|_{F_1} \geq 0$. Then the edge has two corresponding integers called the *slopes* Defined as follows. Choose $P_0, P_1 \in \mathbb{Z}^2$ with $L_{(F_1)}^*(P_0) = 0$ and $L_{(F_1)}^*(P_1) = 1$. Then,

$$s_1^L = \delta_L(\nu_1(P_1) - \nu_1(P_0)) \quad s_2^L = \begin{cases} \delta_L(\nu_2(P_1) - \nu_2(P_0)) & L \text{ inner} \\ \lfloor s_1^L - 1 \rfloor & L \text{ outer} \end{cases}$$

where $\nu_i : \mathbb{Z}^2 \rightarrow \mathbb{Z}$ is the unique affine function which agrees with ν on F_i (recall that the faces are defined such that ν is affine when restricted to each face. Given the slopes, we may consider a sequence of rational numbers $\frac{m_i}{d_i} \in \mathbb{Q}$ such that,

$$s_1^L = \frac{m_0}{d_0} > \frac{m_1}{d_1} > \frac{m_2}{d_2} > \dots > \frac{m_r}{d_r} > \frac{m_{r+1}}{d_{r+1}} \quad \text{and} \quad \begin{vmatrix} m_i & m_{i+1} \\ d_i & d_{i+1} \end{vmatrix} = m_i d_{i+1} - m_{i+1} d_i = 1$$

Then $r(L)$, the minimal length of this sequence, and the denominators d_i of this minimal sequence, are important combinatorial parameter of the edge L . It turns out such a minimal sequence is unique.

Remark. The existence of such a sequence needs some consideration. Take all rational numbers in $[s_1^L, s_2^L] \cap \mathbb{Q}$ with denominators bounded by the largest denominator of s_1^L and s_2^L . This is a shifted Farey series. We define the Farey series F^n to be the ordered sequence of rational numbers with denominator less than or equal to n put in lowest terms. Then, if $\frac{a}{b} < \frac{c}{d}$ are consecutive terms in the Farey series then $\frac{c}{d} - \frac{a}{b} = \frac{1}{bd}$. Therefore,

$$\begin{vmatrix} a & c \\ b & d \end{vmatrix} = ad - bc = 1$$

[Dok18, Remark 3.15] and [HWHB⁺08, Ch. III, Thm. 28, Thm. 29]. Furthermore, if the sequence in $[s_1^L, s_2^L] \cap \mathbb{Q}$ with bounded denominators contains consecutive terms,

$$\frac{a}{b} > \frac{a+c}{b+d} > \frac{c}{d}$$

then we must have,

$$a(b+d) - b(a+c) = ab + ad - ab - bc = ad - bc = 1$$

meaning that $\frac{a}{b} > \frac{b}{d}$ have the required adjacency property and thus $\frac{a+c}{b+d}$ may be removed from the sequence. We will reinterpret this as a blow-down of regular normal crossings models after we state the main theorems describing the structure of such models from the above combinatorial data.

6.2 Main Theorems

We describe the properties of the model \mathcal{C}_Δ over R associated to some polygonal partition of Δ defined by a Laurent polynomial $f \in K[x^{\pm 1}, y^{\pm 1}]$.

Theorem 6.13 (Dor18, Thm. 3.13). Let C be a smooth projective Δ_ν -regular curve birational to U_f for a Δ_ν -regular Laurent polynomial $f \in K[x^{\pm 1}, y^{\pm 1}]$. Then \mathcal{C}_Δ/R is a regular normal crossing model of C and the special fiber \mathcal{C}_κ geometrically decomposes into components as follows:

- (a). each ν -face F of Δ gives a smooth complete curve $\overline{X}_F \times_\kappa \kappa^{\text{sep}}$ over κ^{sep} with multiplicity δ_F and genus $g_F = |\{P \in F^\circ \cap \mathbb{Z}^2 \mid \nu(P) \in \mathbb{Z}\}|$
- (b). each ν -edge L with sequence $\frac{m_i}{d_i} \in \mathbb{Q}$ ($0 \leq i \leq r+1$) gives $|X_L(\kappa^{\text{sep}})|$ chains of length r of closed subschemes intersecting transversally each isomorphic to $\mathbb{P}_{\kappa^{\text{sep}}}^1$ with multiplicities in \mathcal{C}_κ given by $\delta_L d_1, \dots, \delta_L d_r$.

Furthermore, the $\text{Gal}(\kappa^{\text{sep}}/\kappa)$ -action on $\mathcal{C}_\kappa \times_\kappa \kappa^{\text{sep}}$ is given by acting on each component $X_F \times_\kappa \kappa^{\text{sep}}$ and permuting the $\mathbb{P}_{\kappa^{\text{sep}}}^1$ chains via the natural action of $\text{Gal}(\kappa^{\text{sep}}/\kappa)$ on $|X_L(\kappa^{\text{sep}})|$.

Remark. The genus of \overline{X}_F is exactly the number of lattice points interior to the Newton polygon defining $X_F \subset \mathbb{G}_{m,\kappa}^2$ by Baker's theorem. Recall this Newton polygon is the restriction of f to the set $S = \{P \in F \cap \mathbb{Z}^2 \mid \nu(P) \in \mathbb{Z}\}$ so the lattice generated by S only has lattice points where at points of \mathbb{Z}^2 where $\nu(P) \in \mathbb{Z}$ explaining the genus formula above.

Example 6.14. Consider the affine equations $f_1 = t^3x^3 + y^3 + 1$ and $f_2 = tx^3 + y^3 + 1$. Both of these equations have Newton polygon $\Delta = 3\Sigma$ a 3 by 3 triangle and both give the trivial partition Δ_ν of Δ with a single face with one interior lattice point $P = (1, 1)$. However, in the first case the interior point has valuation $\nu(P) = 1$ and, in the second, $\nu(P) = \frac{1}{3}$ so these differ in the number of interior lattice points with integer valuation. In the case of f_1 , all the interior points of Δ have integer valuation and thus $f_1|_F = f_1$ with $\delta_F = 1$. Therefore, $f_1|_F = x^3 + y^3 + 1$ which is an elliptic curve over κ giving a single smooth genus one component in the special fiber. Therefore the curve C_{f_1} over K has good reduction. This is clear under the change of variables $y \mapsto ty$ then we get $f_1 = y^3 + x^3 + 1$ which clearly has good reduction.

However, the second equation $f_2 = ty^3 + x^3 + 1$ has restriction $f_2|_F = ty + x^3 + 1$ since the lattice generated by $S = \{P \in F \cap \mathbb{Z}^2 \mid v(P)\} = \{(0, 0), (1, 0), (2, 0), (3, 0), (0, 3)\}$ is $\Lambda = \mathbb{Z} \oplus 3\mathbb{Z}$ and thus $\delta_F = 3$. Furthermore, $f_2|_F = y + x^3 + 1$ which defines a genus zero curve over κ . Therefore, we see the genus does in fact agree with the integer valued interior points of F . However, the curve C_{f_2} over K is also an elliptic curve and must have genus one. How does this agree with our computation of the special fiber? Notice that the non-integer valuations give chains of genus zero components intersecting the main component corresponding to F which we denote as D . Let C_i for $i = 1, 2, 3$ be these three components (see figure 6.14). Then $D \cdot C_i = 1$ and $C_i \cdot C_j = 0$ for $i \neq j$. Then using, $3D + C_1 + C_2 + C_3 \sim 0$ (recall that D has multiplicity 3 since $\delta_F = 3$) we see that $C_i \cdot C_i = -3$ and $D \cdot D = -1$ so the model constructed for f_2 is a regular proper normal crossings model but *not* the minimal regular model since D is a -1 curve. Finally, using the genus formula,

$$g_{C_2} = 1 + \sum_{i=1}^n m_i \left([\kappa(C_i) : \kappa] (g_{C_i} - 1) - \frac{1}{2} (C_i \cdot C_i) \right)$$

to give,

$$g_{C_2} = 1 + 3(-1 + \frac{1}{2}) + 3(-1 + \frac{3}{2}) = 1$$

$$f = t^3 y^3 + x^3 + 1$$

$$\frac{1}{F_1} \frac{g_1}{F_1}$$

$$f = ty^3 + x^3 + 1$$

$$\frac{1}{F_1} \frac{1}{F_1} \frac{1}{F_1} \frac{3}{F_1}$$

Figure 4: Partitions of the Newton polygons and the associated graphs of the special fibers corresponding to the equations $f_1 = t^3 y^3 + x^3 + 1$ and $f_2 = ty^3 + x^3 + 1$. (Image created via the software Magma¹ using scripts by Tim Dokchitser to compute toric models²).

Theorem 6.15 (Dor18, Thm. 3.13). Let $f \in K[x^{\pm 1}, y^{\pm 1}]$ be any Laurent polynomial defining a 1-dimensional scheme $C_0 = U_f \subset \mathbb{G}_{m,K}^2$. Then \mathcal{C}_Δ/R is a proper flat model of the toric completion $C = C_0^\Delta$ with respect to the Newton polygon $\Delta = \Delta(f)$. The special fiber \mathcal{C}_κ is a union of closed subschemes \overline{X}_F indexed by ν -faces F and chains $X_L \times_\kappa \Gamma_L$ where Γ_L is a union of \mathbb{P}_κ^1 intersecting transversally as follows:

- (a). for each ν -edge F : the scheme \overline{X}_F has multiplicity δ_F and, via Theorem 4.2 are geometrically connected and have arithmetic genus $g_F = |\{P \in F^\circ \cap \mathbb{Z}^2 \mid \nu(P) \in \mathbb{Z}\}|$.
- (b). for each ν -edge L choose a sequence $\frac{m_i}{d_i} \in \mathbb{Q}$ ($0 \leq i \leq r+1$) then let $\Gamma_L = \Gamma_L^1 \cup \dots \cup \Gamma_L^r$ with each Γ_L^i isomorphic to \mathbb{P}_κ^1 embedded with multiplicity $\delta_L d_i$ and meeting transversally where we identify $0 \in \Gamma_L^i$ with $\infty \in \Gamma_L^{i+1}$. If $r = 0$ then let $\Gamma_L = \text{Spec}(k)$.
- (c). The subscheme $X_L \times \{0\} \subset X_L \times \Gamma_L^1$ is identified with $\overline{X}_{F_1} \setminus X_{F_1}$ for the ν -face F_1 bordering L and, when L is inner, likewise $X_L \times \{\infty\} \subset X_L \times \Gamma_L^r$ is identified with $\overline{X}_{F_2} \setminus X_{F_2}$ for the other ν -face F_2 bordering L . These intersections are transversal and, in fact, as a scheme the intersection is $V(\overline{f}_L^{\delta_L}) \subset X_L \subset \overline{X}_F$.

Furthermore, the model \mathcal{C}_Δ is geometrically regular are,

- (a). the smooth locus of X_F , for each ν -face L
- (b). the smooth locus of $X_L \times \Gamma_L$, for each ν -edge L

- (c). the smooth points of $\overline{X}_F \setminus X_F$ corresponding to L when $L \subset \partial F$ is an outer edge with $\delta_L = \delta_F$ and $r = 0$.

Furthermore, if C_0 is Δ_ν -regular then $C = C_0^\Delta$ is smooth and thus the unique smooth proper curve birational to C_0 and \mathcal{C}_Δ/R is a regular normal crossings model of C .

7 Relationships Between Toric Notions of Regularity

We have discussed a number of regularity conditions on curves originating from their compatibility in some sense with a certain set of toric embeddings. The utility of these conditions is the ability to verify them from the equation defining some affine model of the curve in $\mathbb{G}_{m,k}^2$. Although these notions are clearly related, we here show that they are, indeed, inequivalent. In this situation, we have a discrete valued field K with valuation ring R and residue field κ . On the special fiber, we will distinguish between the arithmetic (κ non-algebraically closed) and geometric (κ arithmetically closed) situations. The main result of this section is as follows.

Proposition 7.1. Let C be a smooth curve over K . Then we have the following implications,

$$\begin{array}{ccc} C \text{ is strict } \Delta_\nu\text{-regular} & \implies & C \text{ is nondegenerate} \\ \Downarrow & & \Downarrow \\ C \text{ is } \Delta_\nu\text{-regular} & \implies & C \text{ is weakly nondegenerate} \end{array}$$

Furthermore, no implication is reversible.

The fact that Δ -nondegeneracy implies weak Δ -nondegeneracy is simply an application of Baker's theorem (recall that this notion was created, by design, as a weaker form of Δ -nondegeneracy, hence the name). Likewise, strict Δ_ν -regularity implying Δ_ν -regularity is also a consequence of Baker's theorem since the outer-regular condition introduced in the definition of Δ_ν -regularity is satisfied when each X_F is smooth and X_L is smooth since these imply that \overline{X}_F is smooth as well via Baker's theorem.

Strict Δ_ν -regularity implies that each X_L is smooth thus satisfying the conditions of Δ -nondegeneracy. Finally, That Δ_ν -regularity implies weak nondegeneracy follows from the main theorem since if C_0 is an affine model in $\mathbb{G}_{m,k}^2$ then C_0^Δ is smooth and thus the affine equation is weakly Δ -nondegenerate with the added condition that $\Delta = \Delta(f)$. Notice that the outer-regularity condition in the definition of a Δ_ν -regular equation corresponds exactly to the smoothness hypothesis in weak Δ -regularity. So see that strict Δ_ν -regularity and Δ_ν -regularity of an equation are not equivalent, let $f \in K[x^{\pm 1}, y^{\pm 1}]$ be a weakly Δ -nondegenerate Laurent polynomial with every term having zero valuation. Then, there is a unique face $F = \Delta(f)$ and for each edge we have $\delta_F = \delta_L = 1$. Then f is Δ_ν -regular iff it is outer-regular i.e. $U_f^\Delta \subset \mathbb{T}_\Delta$ is smooth so f is weakly $\Delta(f)$ -nondegenerate. We have seen that weakly Δ -nondegenerate equations need not be Δ -nondegenerate.

7.1 Illustrative Examples

In the arithmetic case, the form of the Galois action on the special fiber comprises an obstruction to having the sort of toric-constructed model described in the previous section. Specifically, the Galois action on the dual graph only permutes “parallel” chains of components isomorphic to \mathbb{P}^1 therefore each component \overline{X}_F for the faces F must be Galois-invariant, in particular, this includes all positive

genus components. Furthermore, note that each component \overline{X}_F is geometrically connected and, by Baker's theorem, smooth when in the Δ_ν -regular case. Therefore, the special fiber of regular normal-crossings models of Δ_ν -regular curves cannot have nontrivial orbits of positive genus irreducible components.

7.1.1 Genus Zero Components

To illustrate this phenomenon, we consider the following example. We consider the equicharacteristic case with a section $\kappa \rightarrow R$. Choose the ambient scheme,

$$\mathbb{P}_R^1 \times_R \mathbb{P}_R^1 = \text{Proj}(R[X_0, X_1]) \times_R \text{Proj}(R[Y_0, Y_1])$$

and an element $q \in \kappa$. Then we consider the closed subscheme,

$$X = V((X_0^2 - qX_1^2)(Y_0^2 - qY_1^2) - \varpi X_0 X_1 Y_0 Y_1) \subset \mathbb{P}_R^1 \times_R \mathbb{P}_R^1$$

where $\varpi \in R$ is the uniformizer. Then $X \rightarrow \text{Spec}(R)$ is a regular normal-crossings model (CHECK THIS) of,

$$X_K = V((X_0^2 - qX_1^2)(Y_0^2 - qY_1^2) - \varpi X_0 X_1 Y_0 Y_1) \subset \mathbb{P}_K^1 \times_K \mathbb{P}_K^1$$

This is a smooth curve in $\mathbb{P}_K^1 \times_K \mathbb{P}_K^1$ of bidegree $(2, 2)$ and thus genus $g = 1$. This curve has an affine model,

$$U = \text{Spec}(k[x, y]/((x^2 - q)(y^2 - q) - \varpi xy)) \subset \mathbb{A}_K^1 \times_K \mathbb{A}_K^1$$

Now we consider the special fiber,

$$X_\kappa = V(X_0^2 - qX_1^2) \cup V(Y_0^2 - qY_1^2) \subset \mathbb{P}_\kappa^1 \times_\kappa \mathbb{P}_\kappa^1$$

The behavior of the special fiber depends of whether $q \in \kappa$ is a square. When q is a non-square, the special fiber has two components C_1, C_2 which intersect at two points,

$$P_\pm = (X_0^2 - qX_1^2, Y_0^2 - qY_1^2, X_0 \mp Y_0)$$

each of order two so $C_i \cdot C_i = -4$ and $[\kappa(C_i) : \kappa] = 2$. Therefore, from the genus formula $g_C = 1$ agreeing with our previous result. Geometrically, each component of the special fiber bifurcates to give four components C_i arranged in a square. Then $C_i \cdot C_i = -2$ since each intersects two other components with a simple intersection so again $g_C = 1$. However, there is a Galois action which flips the square along its diagonal exchanging the opposite pairs of intersection points. In the case that $q \in \kappa$ is a square, say for definiteness $q = 1$, then the special fiber X_κ has the same structure as in the geometric picture except with the Galois action being trivial. It is easy to show that no matter if $q \in \kappa$ is a square or not, the affine equation $f = (x^2 - q)(y^2 - q) - \varpi xy$ is never Δ_ν -regular(SHOW THIS). When $q \in \kappa$ is a non-square, the Galois action on the special fiber is not of the type produced by the previously given toric construction. Therefore, this Galois action is an obstruction to finding a Δ_ν -regular affine equation for X_K despite the fact that we have produced a manifestly Δ -toric affine equation for X_K . On the other hand, when $q \in \kappa$ is a square, while the equation f remains not Δ_ν -regular. However, in this case this a pathology of the specific choice of affine equation rather than the curve X_K . Indeed, performing a change of variables $u_\pm = \frac{1}{2}(X_0 \pm X_1)$ and $v_\pm = \frac{1}{2}(Y_0 \pm Y_1)$ which does correspond automorphism of $\mathbb{P}_K^1 \times_K \mathbb{P}_K^1$ but not of the torus $\mathbb{G}_{m,k}^2$ reflecting the fact that the necessary change of variables must shift the location of the toric divisor in order to be Δ_ν -regular. Then the homogeneous equation becomes,

$$\tilde{f} = 16u_+u_-v_+v_- - \varpi(u_+^2 - u_-^2)(v_+^2 - v_-^2)$$

$$f = (x^2 + 4)y^2 + 4 * txy + 4x^2 + 1$$

$$f = (tx^2 + 4 * t)y^2 + xy + 4 * tx^2 + t$$

Figure 5: The algorithm applied to $f_1 = (x^2 - 1)(y^2 - 1) - txy$ and the change of variables $f_2 = uv - t(x^2 - 1)(y^2 - 1)$ chosen to ensure Δ_ν -regularity. Notice the point of failure of Δ_ν -regularity in the first case is the singularity of the special fiber which is determined by a single face in this affine presentation. Furthermore, note the topology of the special fiber when it is properly computed. Δ_ν -regular models are only capable of producing this special fiber in the geometric case i.e. when the components are Galois fixed which occurs when $q \in \kappa$ is a square. However, regardless of q , the topology of the special fiber is unchanged with the arithmetic information being encoded in the Galois action instead. (Images created via the software Magma¹ using scripts by Tim Dokchitser to compute toric models²).

¹ <https://magma.maths.usyd.edu.au/magma/>

² <https://people.maths.bris.ac.uk/~matyd/newton/>

Taking the affine patch $D_+(u_-) \times D_+(v_-)$ gives an affine model,

$$U = \text{Spec} (k[u, v] / (16uv - \varpi(u^2 - 1)(v^2 - 1)))$$

Furthermore, for $p \neq 2$ this equation is Δ_ν -regular. (ELABORATE ON WHY THIS OCCURS)

7.1.2 Extension to Higher Genus

In order to extend our argument to higher genus curves, we need to apply Riemann-Roch. However, since this example only works in the arithmetic setting we require a slight modification to the standard statement of Riemann-Roch found in Hartshorne [Har77, Thm. IV.1.3]. To ensure there is no confusion, we will provide a proof here.

Theorem 7.2 (Riemann-Roch). Let X be a smooth proper curve over k with $H^0(X, \mathcal{O}_X) = K$ and genus $g = \dim_K H^0(X, \omega_X)$. Then for any line bundle \mathcal{L} ,

$$\chi(\mathcal{L}) = \dim_k H^0(X, \mathcal{L}) - \dim_k H^0(X, \omega_X \otimes_{\mathcal{O}_X} \mathcal{L}^\vee) = \deg \mathcal{L} + [K : k](1 - g)$$

Where $\deg \mathcal{L}$ is defined in the arithmetic case as follows. Choose a nonzero meromorphic section $s \in H^0(X, \mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{K}_X)$ and a local trivialization $\{(U_i, s_i)\}$ with $s_i \in \mathcal{L}(U_i)$ such that $\mathcal{O}_{U_i} \xrightarrow{s_i} \mathcal{L}|_{U_i}$ is

an isomorphism. Then define,

$$\deg \mathcal{L} = \sum_{P \in X} [\kappa(P) : k] \operatorname{ord}_P(s/s_i)$$

for some i with $P \in U_i$.

Proof. First, note that by Serre duality, $H^1(X, \mathcal{L}) \cong H^0(X, \omega_X \otimes_{\mathcal{O}_X} \mathcal{L}^\vee)^\vee$ so,

$$\chi(\mathcal{L}) = \dim_k H^0(X, \mathcal{L}) - \dim_k H^1(X, \mathcal{L}) = \dim_k H^0(X, \mathcal{L}) - \dim_k H^0(X, \omega_X \otimes_{\mathcal{O}_X} \mathcal{L}^\vee)$$

Since X is smooth, every line bundle \mathcal{L} is $\mathcal{O}_X(D)$ for some divisor D . However, since X is smooth, the map $c_1 : \operatorname{Pic}(X) \rightarrow \operatorname{Cl}(X)$ is an isomorphism sending,

$$\mathcal{L} \mapsto \sum_{P \in X} [P] \operatorname{ord}_P(s_i/s)$$

where the sections s_i and s are as before. Therefore, for a divisor,

$$D = \sum_{P \in X} n_P [P]$$

if we define the degree (including the arithmetic degrees of extensions),

$$\deg D = \sum_{P \in X} [\kappa(P) : k] n_P$$

then clearly $\deg \mathcal{L} = \deg c_1(\mathcal{L})$. Since c_1 is an isomorphism, it suffices to show that,

$$\chi(\mathcal{O}_X(D)) = \deg D + 1 - g$$

However, every divisor D can be obtained by a finite sequence of adding or subtracting points $[P]$ from $D = 0$ i.e. from the line bundle \mathcal{O}_X . Furthermore,

$$\chi(\mathcal{O}_X) = \dim_k H^0(X, \mathcal{O}_X) - \dim_k H^1(X, \mathcal{O}_X) = [K : k](1 - g)$$

since, by Serre duality, $\dim_k H^1(X, \mathcal{O}_X) = \dim_k H^0(X, \omega_X) = [K : k]g$ because $\dim_K H^0(X, \omega_X) = g$ by definition. Therefore, to proceed by induction, it suffices to show that,

$$\chi(\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{O}_X(\pm P)) = \chi(\mathcal{L}) \pm [\kappa(P) : k]$$

since $\deg(\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{O}_X(\pm P)) = \deg \mathcal{L} \pm [\kappa(P) : k]$. Consider the exact sequence,

$$0 \longrightarrow \mathcal{O}_X(-P) \longrightarrow \mathcal{O}_X \longrightarrow (\iota_P)_* \kappa(P) \longrightarrow 0$$

where $\kappa(P)$ is the structure sheaf of P as a reduced closed subscheme. Then tensoring by \mathcal{L} we get,

$$0 \longrightarrow \mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{O}_X(-P) \longrightarrow \mathcal{L} \longrightarrow (\iota_P)_* \kappa(P) \longrightarrow 0$$

since \mathcal{L} is locally free so $(\iota_P)_*\kappa(P) \otimes_{\mathcal{O}_X} \mathcal{L} = (\iota_P)_*\kappa(P)$. Thus,

$$\chi(\mathcal{L}) = \chi(\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{O}_X(-P)) + \chi((\iota_P)_*\kappa(P))$$

however

$$\chi(\kappa(P)) = \dim_k H^0(X, (\iota_P)_*\kappa(P)) - \dim_k H^1(X, (\iota_P)_*\kappa(P)) = \dim_k \kappa(P) = [\kappa(P) : k]$$

Therefore,

$$\chi(\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{O}_X(-P)) = \chi(\mathcal{L}) - [\kappa(P) : k]$$

Likewise, replacing \mathcal{L} by $\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{O}_X(P)$ we see that,

$$\chi(\mathcal{L} \otimes_{\mathcal{O}_X} \mathcal{O}_X(P)) = \chi(\mathcal{L}) + [\kappa(P) : k]$$

proving the theorem. \square

Remark. If $s \in H^0(X, \mathcal{L})$ is a nonzero global section, then we can compute $\deg \mathcal{L}$ using the vanishing of s which is effective since s has no poles. Thus, $\deg \mathcal{L} \geq 0$. In particular, applying Riemann-Roch to ω_X we see that $\deg \omega_X = \chi(\omega_X) - \chi(\mathcal{O}_X) = g - 1 - (1 - g) = 2g - 2$. Therefore, if $\deg \mathcal{L} > 2g - 2$ then $\deg(\omega_X \otimes_{\mathcal{O}_X} \mathcal{L}^\vee) = 2g - 2 - \deg \mathcal{L} \leq 0$ which implies that $H^0(X, \omega_X \otimes_{\mathcal{O}_X} \mathcal{L}^\vee) = 0$ so by Riemann-Roch applied to \mathcal{L} we find,

$$\dim_k H^0(X, \mathcal{L}) = \deg \mathcal{L} + 1 - g$$

Now we consider the following example. Take the field $K = \mathbb{F}_p(t)$ with valuation ring $R = \mathbb{F}_p[t]_{(t)}$ and residue field $\kappa = \mathbb{F}_p$. Given an elliptic curve C_K over K with good reduction C over κ so we may take a smooth model \mathcal{C} over R . For example, let $q \in \mathbb{F}_p^\times$ be a generator, take

$$C_K = \text{Proj} (K[X, Y, Z]/(Y^2Z - X(X^2 - qZ^2)))$$

we may take the model,

$$\mathcal{C} = \text{Proj} (R[X, Y, Z]/(Y^2Z - X(X^2 - qZ^2)))$$

which is smooth and proper over R for $p \neq 2$. Clearly $\mathcal{C}_K = C_K$ and the special fiber \mathcal{C}_κ is the smooth reduction. Now let P be a \mathbb{F}_{p^2} -point of C which is not a \mathbb{F}_p -rational point, e.g. take $P = (X^2 - qZ^2, Y)$ which has $\kappa(P) = \mathbb{F}_{p^2}$. Recall that $\omega_C = \mathcal{O}_C$ since C is an abelian variety and $g = 1$ so if $\deg \mathcal{L} > 0$ we know that $\dim_k H^0(C, \mathcal{L}) = \deg \mathcal{L}$ by Riemann-Roch. Then consider the line bundle $\mathcal{L} = \mathcal{O}_C(P)$ then $\deg \mathcal{L} = [\kappa(P) : k] = 2$. Therefore, we can choose linearly independent sections $s_0, s_1 \in H^0(C, \mathcal{L})$ where the section $s_0 : \mathcal{O}_C \rightarrow \mathcal{L}$ is the canonical section defining the closed subscheme P from the inclusion $\mathcal{L}^\vee \rightarrow \mathcal{O}_C$ of the sheaf of ideals of P . Then s_0 vanishes exactly on P i.e. the closed subscheme $V(s_0) = P$. Now $\text{div}(s_1)$ is an effective divisor of degree 2 so either $\text{div}(s_1) = [P]$ or $\text{div}(s_1) = [Q_1] + [Q_2]$ for \mathbb{F}_p -rational points Q_1, Q_2 or $\text{div}(s_1) = [Q]$ where $Q \neq P$ is an order-2 point. However, if $\text{div}(s_1) = [P]$ then s_1 must have vanishing order 1 since it has degree 2 which implies that $s_0/s_1 \in H^0(C, \mathcal{O}_C^\times)$ contradicting the fact that s_0 and s_1 are independent in $H^0(C, \mathcal{L})$ (over $H^0(C, \mathcal{O}_C) = \kappa$). The takeaway is that s_0 only vanishes at P and s_1 does not vanish at P . Notice, since we are in equicharacteristic the map $\kappa \rightarrow R$, our model is simply a base-change,

$$\mathcal{C} = C \times_{\text{Spec}(\kappa)} \text{Spec}(R)$$

so we get a line bundle $\mathcal{L}' = \pi_1^* \mathcal{L}$ on \mathcal{C} and, by Kunneth, $H^0(\mathcal{C}, \mathcal{L}') = H^0(\mathcal{C}, \mathcal{L}) \otimes_{\kappa} R$.

We now construct our example as follows. Consider the scheme $\mathcal{C} \times_R \mathcal{C}$ and denote the projection maps, $\pi_i : \mathcal{C} \times_R \mathcal{C} \rightarrow \mathcal{C}$. Take the section,

$$\pi_1^* s_0 \otimes \pi_2^* s_0 - t \pi_1^* s_1 \otimes \pi_2^* s_1 \in H^0(\mathcal{C} \times_R \mathcal{C}, \pi_1^* \mathcal{L}' \otimes_{\mathcal{O}_X} \pi_2^* \mathcal{L}')$$

on the bundle $\mathcal{L}' \boxtimes \mathcal{L}' := \pi_1^* \mathcal{L}' \otimes_{\mathcal{O}_X} \pi_2^* \mathcal{L}'$. We will write this section as $q = s_0 \boxtimes s_0 - t s_1 \boxtimes s_1$. Then we take,

$$X = V(s_0 \boxtimes s_0 - t s_1 \boxtimes s_1) \subset \mathcal{C} \times_R \mathcal{C}$$

I claim that $X \rightarrow \text{Spec}(R)$ is a regular proper model of,

$$X_K = V(s_0 \boxtimes s_0 - t s_1 \boxtimes s_1) \subset C_K \times_K C_K$$

Here C_K is an elliptic curve over K and I claim that X_K is a smooth projective curve over K of genus $g = 9$. To show this, we compute an affine curve birational to X_K . First, we compute the sections $s_0, s_1 \in H^0(X, \mathcal{O}_X(P)) \subset K(C)$. Recall that,

$$H^0(X, \mathcal{O}_X(P)) = \{f \in K(X) \mid \text{div}(f) + P \geq 0 \text{ or } f = 0\}$$

and the canonical section is $s_0 = 1$. Then take $s_1 = \frac{Z}{Y}$ which has,

$$\text{div}(s_1) = 2[\infty] - [P]$$

where $[\infty] = [0 : 1 : 0]$ is the point at infinity in the standard $(x, y) = (\frac{X}{Z}, \frac{Y}{Z})$ coordinates¹. To compute $\text{div}(s_1)$, note that $\text{ord}_P(y) = 1$ because $y \in (x^2 - q, y)$ but $y \notin (x^2 - q, y)^2$, furthermore, in $D_+(Y)$ and local coordinates $(x, z) = (\frac{X}{Y}, \frac{Z}{Y})$ then $s_1 = z$ and $\text{ord}_{\infty}(z) = 2$ because $z \in (x, z)$ and $z \in (x, z)^2$ since $z = x(x^2 - qz^2) \in (x, z)^2$.

We choose the affine patch, $U_K \times_K U_K \subset C_K \times_K C_K$ which is defined by,

$$U_K = C_K \cap D(Z) = \text{Spec}(K[x, y]/(y^2 - x(x^2 - q)))$$

Since $\text{div}(\frac{Y}{Z}) = [P] - 2[\infty]$, applying the exact sequence,

$$[\infty] \cdot \mathbb{Z} \longrightarrow \text{Cl}(C_K) \longrightarrow \text{Cl}(U_K) \longrightarrow 0$$

we see that $[P] \in \text{Cl}(U)$ is principal $[P] = \text{div}(\frac{Z}{Y})|_U$. Therefore, $\mathcal{O}_{C_K}(P) \cong \mathcal{O}_{C_K}$ via the isomorphism, $1 \mapsto \frac{Y}{Z}$ meaning that $s_0 \mapsto \frac{Y}{Z}$ and $s_1 \mapsto 1$ in \mathcal{O}_{C_K} . Therefore, the affine open,

$$V_K = V(s_0 \boxtimes s_0 - t s_1 \boxtimes s_1) \subset U_K \times_K U_K$$

is explicitly,

$$V_K = \text{Spec}(K[x_1, y_1, x_2, y_2]/(y_1^2 - x_1(x_1^2 - q), y_2^2 - x_2(x_2^2 - q), y_1 y_2 - t))$$

¹For $P = (X^2 - gZ^2, Y)$ the intuitive choice $s_1 = (\frac{X^2}{Z^2} - q)^{-1}$ will not give a section of $\mathcal{O}_C(P)$ because its vanishing order is too large, in fact, $\text{ord}_P(\frac{X^2}{Z^2} - q) = 2$. To see this, consider the affine patch $D_+(Z)$ with coordinates $(x, y) = (\frac{X}{Z}, \frac{Y}{Z})$ and the section $(x^2 - q) \in A_P$ where $A = \kappa[x, y]/(y^2 - x(x^2 - q))$. Let $\mathfrak{m} = PA_P$ then clearly $(x^2 - q) \in \mathfrak{m}$ but also $(x^2 - q) \in \mathfrak{m}^2$ because $x^{-1}y^2 = (x^2 - q) \in \mathfrak{m}^2$ since $y \in \mathfrak{m}$ and $x \notin P$.

(FIND PLANE CURVE MODEL) In the software sage², we can compute the genus $g = 5$ from this affine presentation³. Now consider the special fiber $X_\kappa = V(s_0 \boxtimes s_0) \subset C \times_k C$ given by the base change under the map $R \rightarrow R/(t) = \kappa$ sending $t \mapsto 0$. Therefore, the irreducible components C_1, C_2 are each isomorphic to $C \times_{\mathbb{F}_p} \mathbb{F}_{p^2}$ and as effective Cartier divisors $X_\kappa = C_1 + C_2$ with multiplicity one since the special fiber is reduced. The intersection number between these components is $C_1 \cdot C_2 = 4$ because these components intersect at two points $P_\pm = (X_0^2 - qZ_0^2, Y_0, X_1^2 - qZ_1^2, Y_1, X_0 \mp X_1)$ each a point of degree 2. Therefore, using $C_i \cdot (C_1 + C_2) = 0$ we find that $C_i \cdot C_i = -4$. Therefore, applying the genus formula,

$$g_C = 1 + \sum_{i=1}^n m_i \left([\kappa(C_i) : \kappa](g_{C_i} - 1) - \frac{1}{2}(C_i \cdot C_i) \right)$$

we get $g_C = 1 + 4 = 5$ since $g_{C_i} = 1$ and $m_i = 1$ because each component is a reduced elliptic curve.

Geometrically, each component bifurcates to give a square with each side a reduced elliptic curve divisor isomorphic to C . The Galois group acts on this square by reflection across the diagonals. Since X does not contain any exceptional curves of the first kind, it is the minimal model of V (and in fact the minimal regular normal crossings model since X_κ happens to be a normal crossings divisor). Therefore, any proper regular normal crossings model of V must be a blowup of X and in particular its special fiber must contain two pairs of Galois conjugate elliptic curves. Therefore, no Δ_ν -regular affine equation for V can exist since such an equation would define a proper regular normal crossings model of V with trivial Galois action on positive genus components.

²<http://www.sagemath.org/>

³In fact, asking sage to compute the genus of the above affine curve produces $g = 10$. This reflects that sage computes the genus *over the field of definition* where as we take the base field here to be $k = H^0(X, \mathcal{O}_X)$ and define $g = \dim_k H^0(X, \Omega_X^1)$. In our example here, since P is an order two point, $H^0(X, \mathcal{O}_X) = \mathbb{F}_{p^2}$ and thus, the correct genus is computed as,

$$g(X) = \dim_\kappa H^0(X, \Omega_X^1) / \dim_\kappa H^0(X, \mathcal{O}_X) = 10/2 = 5$$

8 Appendix

8.1 Curves and Genera

Lemma 8.1. Let X be a integral scheme proper over k then $K = H^0(X, \mathcal{O}_X)$ is a finite field extension of k and for any coherent \mathcal{O}_X -module \mathcal{F} , the cohomology $H^p(X, \mathcal{F})$ is a finite-dimensional $H^0(X, \mathcal{O}_X)$ -module.

Proof. Since \mathcal{O}_X is coherent, and X is proper over k so $K = H^0(X, \mathcal{O}_X)$ is a finite k -module. However, since X is integral $H^0(X, \mathcal{O}_X)$ is a domain but a finite k -algebra domain is a field and we see K/k is a finite extension of fields. Furthermore, the $\mathcal{O}_X(X)$ -module structure on $H^p(X, \mathcal{F})$ gives it a K -module structure. Since X is proper over k then $H^p(X, \mathcal{F})$ is a finite k -module and thus finite as a K -module. \square

Remark. Unfortunately, when k is not algebraically closed then we may not have $H^0(X, \mathcal{O}_X) = k$ even for smooth projective varieties. Therefore, some caution must be taken in defining numerical invariants of the curve such as genus. However, by Tag 0BUG, whenever X is proper geometrically integral then indeed $H^0(X, \mathcal{O}_X) = k$. Furthermore, for proper X if $H^0(X, \mathcal{O}_X) \neq k$ then X cannot be geometrically connected by Tag 0FD1.

Definition 8.2. Let C be a smooth proper curve over k with $H^0(C, \mathcal{O}_C) = k$. Then we define $g(C) := \dim_k H^0(X, \Omega_{C/k})$. If C is any curve over k then there is a unique smooth proper curve S over k which is k -birational to C . Then we define $g(C) := g(S)$.

Remark. By definition, the genus of a curve is clearly a birational invariant since there is a unique smooth complete curve in every birational equivalence class of curves.

Remark. There is a slight subtlety in this definition in the case of a non-perfect base field. It is always true that we can find a proper *regular* curve C in each birational equivalence class however when k is non-perfect the curve C may not be smooth. However, under a finite purely separable extension K/k , we can ensure that C_K admits a smooth proper model. Then we define $g(C) := g(C_K)$ in the case that C_K is a curve. The only thing that can go wrong is when C is not geometrically irreducible since then C_K will not be integral.

Definition 8.3. The *arithmetic genus* $g_a(C)$ of a proper curve C over k with $H^0(C, \mathcal{O}_C) = k$ is,

$$g_a(C) := \dim_k H^1(X, \mathcal{O}_C)$$

By Serre duality, if C is smooth then $H^0(C, \Omega_C) = H^1(C, \mathcal{O}_C)^\vee$ meaning that $g_a(C) = g(C)$.

Remark. The arithmetic genus depends on the projective compactification and singularities meaning it will not be a birational invariant unlike the (geometric) genus.

Example 8.4. Let $k = \mathbb{F}_p(t)$ for an odd prime $p = 2k + 1$ and consider the curve,

$$C = \text{Spec}(k[x, y]/(y^2 - x^p - t))$$

which is regular but not smooth at $P = (y, x^p - t)$. Consider the purely inseparable extension $K = \mathbb{F}_p(t^{1/p})$. Then $C_K = \text{Spec}(K[x, y]/(y^2 - (x - t^{1/p})^p)) \cong \text{Spec}(K[x, y]/(y^2 - x^p))$. Taking the normalization of C_K gives $\mathbb{A}_K^1 \rightarrow C_K$ via $t \mapsto (t^p, t^2)$. This is birational since the following ring map is an isomorphism,

$$(K[x, y]/(y^2 - x^p))_x \rightarrow K[t]_t$$

sending $x \mapsto t^2$ and $y \mapsto t^p$ which has an inverse $t \mapsto y/x^k$ since $x \mapsto t^2 \mapsto y^2/x^{2k} = x$ and $y \mapsto t^p \mapsto y^p/x^{kp} = y(y^{2k}/x^{pk}) = y$ and $t \mapsto y/x^k \mapsto t^{p-2k} = t$.

Therefore, $C_K \xrightarrow{\sim} \mathbb{P}_K^1$ so $g(C) = g(C_K) = 0$. However, consider the projective closure,

$$\overline{C} = \text{Proj} (k[X, Y, Z]/(Y^2 Z^{p-2} - X^p - tZ^p))$$

then $\overline{C} \hookrightarrow \mathbb{P}_k^2$ is a Cartier divisor (since \mathbb{P}_k^2 is locally factorial) so we find that $H^0(\overline{C}, \mathcal{O}_{\overline{C}}) = k$ and $\dim_k H^1(\overline{C}, \mathcal{O}_{\overline{C}}) = \frac{1}{2}(p-1)(p-2) = k(2k-1)$ since its sheaf of ideals is $\mathcal{O}_{\mathbb{P}_k^2}(-p)$. Then $p = 3$ we expect this to be an elliptic curve and we do see $g_a(\overline{C}) = 1$. However, $g(\overline{C}) = 0$ and correspondingly C is not smooth due to the positive characteristic phenomenon.

Lemma 8.5. Suppose that $f : X \rightarrow Y$ is a finite birational morphism of n -dimensional irreducible Noetherian schemes. Then $H^n(Y, \mathcal{O}_Y) \twoheadrightarrow H^n(X, \mathcal{O}_X)$ is surjective.

Proof. The map f must restrict on some open subset $U \subset X$ to an isomorphism $f|_U : U \rightarrow V$. Thus, the sheaf map $f^\# : \mathcal{O}_Y \rightarrow f_* \mathcal{O}_X$ restricts on V to an isomorphism $\mathcal{O}_Y|_V \xrightarrow{\sim} (f_* \mathcal{O}_X)|_V$. We factor this map into two exact sequences,

$$0 \longrightarrow \mathcal{K} \longrightarrow \mathcal{O}_Y \longrightarrow \mathcal{I} \longrightarrow 0$$

$$0 \longrightarrow \mathcal{I} \longrightarrow f_* \mathcal{O}_X \longrightarrow \mathcal{C} \longrightarrow 0$$

with $\mathcal{K} = \ker(\mathcal{O}_Y \rightarrow f_* \mathcal{O}_X)$ and $\mathcal{C} = \text{coker}(\mathcal{O}_Y \rightarrow f_* \mathcal{O}_X)$ and $\mathcal{I} = \text{Im}(\mathcal{O}_Y \rightarrow f_* \mathcal{O}_X)$. Taking cohomology and using that it vanishes in degree above n we get,

$$H^{n-1}(Y, \mathcal{I}) \longrightarrow H^n(Y, \mathcal{K}) \longrightarrow H^n(Y, \mathcal{O}_Y) \twoheadrightarrow H^n(Y, \mathcal{I}) \longrightarrow 0$$

$$H^{n-1}(Y, \mathcal{C}) \longrightarrow H^n(Y, \mathcal{I}) \longrightarrow H^n(X, \mathcal{O}_X) \twoheadrightarrow H^n(X, \mathcal{C}) \longrightarrow 0$$

where we have used that $f : X \rightarrow Y$ is affine to conclude that $H^p(Y, f_* \mathcal{F}) = H^p(Y, \mathcal{F})$ for any quasi-coherent \mathcal{O}_X -module \mathcal{F} . Furthermore, $\mathcal{C}|_V = 0$ so $\text{Supp}_{\mathcal{O}_Y}(\mathcal{C}) \subset X \setminus V$ but \mathcal{C} is coherent so the support is closed. Since V is dense open, \mathcal{C} is supported in positive codimension so $H^n(Y, \mathcal{C}) = 0$ (since $H^n(S, \mathcal{C})$ vanishes due to dimension on the closed subscheme $S = \text{Supp}_{\mathcal{O}_X}(\mathcal{C})$ on which \mathcal{C} is supported). Thus we have,

$$H^n(Y, \mathcal{O}_Y) \twoheadrightarrow H^n(Y, \mathcal{I}) \twoheadrightarrow H^n(Y, \mathcal{I}) \twoheadrightarrow H^n(X, \mathcal{O}_X)$$

proving the proposition. □

Corollary 8.6. Let S and C be k -birational geometrically integral (DO I NEED THIS?) proper curves over k where S is smooth. Then the genera satisfy,

- (a). $g_a(C) \geq g_a(S)$
- (b). $g(C) = g(S)$
- (c). $g(C) \leq g_a(C)$ with equality if and only if C is smooth.

Proof. Given a birational map $S \xrightarrow{\sim} C$ we can extend it to a birational morphism $S \rightarrow C$ since S is regular. The morphism $S \rightarrow C$ is automatically finite since it is a non-constant map of proper curves. Then the previous lemma implies that $g_a(S) \leq g_a(C)$. (b). follows from the definition of $g(C)$. The third follows from the fact that $g(S) = g_a(S)$ because of Serre duality,

$$H^1(S, \mathcal{O}_S) \cong H^0(S, \Omega_{S/k})^\vee$$

using that S is smooth. Then we see that $g(C) = g(S) = g_a(S) \leq g_a(C)$ proving the inequality part of (c). Finally, if C is smooth we see by Serre duality that $g(C) = g_a(C)$. Conversely, suppose that $g(C) = g_a(C)$ then $g_a(C) = g(C) = g(S) = g_a(S)$ and consider the map $f : S \rightarrow C$ which is finite birational map of integral schemes over k . In particular, f is affine so for each $y \in C$ we may choose an affine open $y \in V \subset C$ whose preimage $U = f^{-1}(V)$ is also affine. On sheaves, this gives a map of domains $\mathcal{O}_C(V) \rightarrow \mathcal{O}_S(U)$ which localizes to an isomorphism on the fraction fields. However, the localization map of a domain is injective so $\mathcal{O}_C(V) \hookrightarrow \mathcal{O}_S(U)$ is an injection. This shows that $\mathcal{O}_C \rightarrow f_*\mathcal{O}_S$ is an injection of sheaves which we extend to an exact sequence,

$$0 \longrightarrow \mathcal{O}_C \longrightarrow f_*\mathcal{O}_S \longrightarrow \mathcal{C} \longrightarrow 0$$

Note that $f : S \rightarrow C$ induces an isomorphism $H^0(C, \mathcal{O}_C) \xrightarrow{\sim} H^0(S, \mathcal{O}_S)$ since both are isomorphic to k when the curves are geometrically integral (DO I NEED THIS, is saying they are birational enough to conclude this isomorphism?). Then the long exact sequence of cohomology gives,

$$0 \rightarrow H^0(C, \mathcal{O}_C) \xrightarrow{\sim} H^0(S, \mathcal{O}_S) \rightarrow H^0(X, \mathcal{C}) \rightarrow H^1(C, \mathcal{O}_C) \xrightarrow{\sim} H^1(S, \mathcal{O}_S) \rightarrow H^1(S, \mathcal{C}) = 0$$

I claim that $H^1(S, \mathcal{C}) = 0$. Since f is birational, \mathcal{C} is supported in codimension one. Thus, the map $H^1(C, \mathcal{O}_C) \rightarrow H^1(S, \mathcal{O}_S)$ is surjective but $g_a(C) = g_a(S)$ so these vectorspaces have the same dimension so $H^1(C, \mathcal{O}_C) \xrightarrow{\sim} H^1(S, \mathcal{O}_S)$ is an isomorphism. Thus, from the exact sequence we have $H^0(X, \mathcal{C}) = 0$. However, $\text{Supp}_{\mathcal{O}_C}(\mathcal{C})$ is a closed (\mathcal{C} is coherent) dimension zero subset i.e. finitely many discrete closed points. However, a sheaf supported on a discrete set of points is zero iff it has no global sections. Therefore, $\mathcal{C} = 0$ so $\mathcal{O}_C \xrightarrow{\sim} f_*\mathcal{O}_S$. In particular $\mathcal{O}_C(V) \xrightarrow{\sim} \mathcal{O}_S(U)$ is an isomorphism which implies that the map of affine schemes $f|_U : U \rightarrow V$ is an isomorphism. Since the affine opens V cover C we see that $f : S \rightarrow C$ is an isomorphism. In particular, C is smooth. \square

8.2 The Locus on Which Morphisms Agree

Lemma 8.7. Let $(R, \mathfrak{m}, \kappa)$ be a local ring. Then for schemes X there is a natural bijection,

$$\text{Hom}_{\mathbf{Sch}}(\text{Spec}(R), X) \cong \{x \in X \text{ and local map } \mathcal{O}_{X,x} \rightarrow R\}$$

Proof. Given $\text{Spec}(R) \rightarrow X$ we automatically get $\mathfrak{m} \mapsto x$ and $\mathcal{O}_{X,x} \rightarrow R_{\mathfrak{m}} = R$. Now, note that taking any affine open neighborhood $x \in \text{Spec}(A) \subset X$ and then $A \rightarrow A_{\mathfrak{p}} = \mathcal{O}_{X,x}$ to give $\text{Spec}(\mathcal{O}_{X,x}) \rightarrow \text{Spec}(A) \rightarrow X$. Clearly, this map sends $\mathfrak{m}_x \mapsto x$ and at \mathfrak{m}_x has stalk map $\text{id} : \mathcal{O}_{X,x} \rightarrow \mathcal{O}_{X,x}$ since it is the localization at \mathfrak{p} of $A \rightarrow A_{\mathfrak{p}}$.

Thus we get an inverse as follows. Given a point $x \in X$ and a local map $\phi : \mathcal{O}_{X,x} \rightarrow R$ then take,

$$\text{Spec}(R) \rightarrow \text{Spec}(\mathcal{O}_{X,x}) \rightarrow X$$

This is inverse since $\mathfrak{m} \mapsto \mathfrak{m}_x$ (because $\mathcal{O}_{X,x} \rightarrow \mathfrak{m}_x$ is local) and $\mathfrak{m}_x \mapsto x$ and the stalk at \mathfrak{m} gives $\mathcal{O}_{X,x} \xrightarrow{\text{id}} \mathcal{O}_{X,x} \xrightarrow{\phi} R$.

Finally, I claim that any $f : \text{Spec}(R) \rightarrow X$ factors through $\text{Spec}(R) \rightarrow \text{Spec}(\mathcal{O}_{X,x}) \rightarrow X$ and thus is reconstructed from $x \in X$ and $\mathcal{O}_{X,x} \rightarrow R$. Choose an affine open neighborhood $x \in \text{Spec}(A) \subset X$ then consider $f^{-1}(\text{Spec}(A))$ which is open in $\text{Spec}(R)$ and contains the unique closed point $\mathfrak{m} \in \text{Spec}(R)$ so there is some $f \in R$ s.t. $\mathfrak{m} \in D(f) \subset f^{-1}(\text{Spec}(A))$ so $f \notin \mathfrak{m}$ so $f \in R^\times$ and thus $D(f) = \text{Spec}(R)$. Therefore, we get a map $\text{Spec}(R) \rightarrow \text{Spec}(A)$ and thus $\phi : A \rightarrow R$ where $\phi^{-1}(\mathfrak{m}) = \mathfrak{p} = x$ so $A \setminus \mathfrak{p}$ is mapped inside R^\times so this map factors through $A \rightarrow A_{\mathfrak{p}} \rightarrow R$ giving the desired factorization $\text{Spec}(R) \rightarrow \text{Spec}(\mathcal{O}_{X,x}) \rightarrow \text{Spec}(A) \rightarrow X$. \square

Definition 8.8. The locus Z on which two maps $f, g : X \rightarrow Y$ over S agree is given as the pullback,

$$\begin{array}{ccc} Z & \xrightarrow{\quad} & Y \\ \downarrow & \lrcorner & \downarrow \Delta_Y \\ X & \xrightarrow{F} & Y \times_S Y \end{array}$$

with $F = (f, g)$. Furthermore $Z \rightarrow X$ is an immersion.

Lemma 8.9. Topologically, the locus on which S -morphisms $f, g : X \rightarrow Y$ agree is,

$$Z = \{x \in X \mid f(x) = g(x) \text{ and } f_x = g_x : \kappa(f(x)) \rightarrow \kappa(x)\}$$

Proof. On some S -subscheme $G \subset X$, the maps $f|_G = g|_G$ agree iff there exists $G \rightarrow Y$ such that,

$$\begin{array}{ccc} G & \dashrightarrow & Y \\ \downarrow & & \downarrow \Delta \\ X & \xrightarrow{F} & Y \times_S Y \end{array}$$

commutes. In particular, for any point $x \in X$ consider $\iota : \text{Spec}(\kappa(x)) \rightarrow X$ then $f \circ \iota = g \circ \iota$ iff $f(x) = g(x)$ and $f_x = g_x : \kappa(f(x)) \rightarrow \kappa(x)$. Consider a point $z \in Z$ and $\text{Spec}(\kappa(z)) \rightarrow Z$, such a point is equivalent to giving a diagram,

$$\begin{array}{ccccc} & & \text{Spec}(\kappa(z)) & & \\ & \searrow & \downarrow & \swarrow & \\ & & Z & \xrightarrow{\quad} & Y \\ & \searrow & \downarrow & \lrcorner & \downarrow \Delta_Y \\ & & X & \xrightarrow{F} & Y \times_S Y \end{array}$$

However, $\iota : Z \rightarrow X$ is an immersion so $f_x : \kappa(f(x)) \xrightarrow{\sim} \kappa(x)$ is an isomorphism. Therefore, points $\text{Spec}(\kappa(z)) \rightarrow Z$ of z , are exactly points of X for which a lift $\text{Spec}(\kappa(x)) \rightarrow Y$ exists i.e. points such that f and g agree in the required way. \square

Lemma 8.10. If $f : X \rightarrow Y$ is an immersion then $f_x : \mathcal{O}_{Y,f(x)} \twoheadrightarrow \mathcal{O}_{X,x}$ is injective for each $x \in X$ and $f_x : \kappa(f(x)) \xrightarrow{\sim} \kappa(x)$ is an isomorphism.

Proof. First note that $f^\# : \mathcal{O}_Y \rightarrow f_*\mathcal{O}_X$ is surjective by definition (surjective for the closed immersion factor and isomorphism for the open immersion factor). Thus we get an injection

$f_x : \mathcal{O}_{Y,y} \rightarrow (f_*\mathcal{O}_X)_{f(x)}$. Furthermore, topologically, $f : X \rightarrow Y$ is a homomorphism onto its image so for any open $U \subset X$ there exists an open $V \subset Y$ s.t. $U = f^{-1}(V)$ showing that,

$$(f_*\mathcal{O}_X)_{f(x)} = \varinjlim_{f(x) \in V} \mathcal{O}_X(f^{-1}(V)) = \varinjlim_{x \in U} \mathcal{O}_X(U) = \mathcal{O}_{X,x}$$

Finally, since $f_x : \mathcal{O}_{Y,f(x)} \rightarrow \mathcal{O}_{X,x}$ is local we get $f_x : \kappa(f(x)) \rightarrow \kappa(x)$ which is a surjection of fields and thus an isomorphism. \square

Lemma 8.11. If $Y \rightarrow S$ is separated then the locus on which $f, g : X \rightarrow Y$ over S agree is closed.

Proof. Since $X \rightarrow S$ is separated, $\Delta_{Y/S} : Y \rightarrow Y \times_S Y$ is a closed immersion. So $Z \rightarrow X$ is the base change of a closed immersion and thus a closed immersion. \square

Lemma 8.12. Let X be a reduced and Y be a separated scheme over S and $f, g : X \rightarrow Y$ be morphism over S . If $f \circ j = g \circ j$ agree on a dense subscheme $j : G \hookrightarrow X$ then $f = g$.

Proof. Consider $F = (f, g) : X \rightarrow Y \times_S Y$. Since $\Delta : Y \rightarrow Y \times_S Y$ is a closed immersion (by separateness). Then $F^{-1}(\Delta)$ is the locus on which $f = g$ which is closed because $\Delta : Y \rightarrow Y \times_S Y$ is a closed immersion. Since $f|_G = g|_G$ we get a diagram,

$$\begin{array}{ccccc} & & G & & \\ & \swarrow & & \searrow & \\ & Z & \xrightarrow{\tilde{F}} & Y & \\ & \downarrow \iota & \lrcorner & \downarrow \Delta_Y & \\ & X & \xrightarrow{F} & Y \times_S Y & \end{array}$$

Since $\iota : Z \hookrightarrow X$ is a closed immersion with dense image, $Z \hookrightarrow X$ is surjective. By the following, $\iota : Z \rightarrow X$ is an isomorphism. Thus, $F = F \circ \iota \circ \iota^{-1} = \Delta_Y \circ \tilde{F} \circ \iota^{-1}$. By the universal property of maps $X \rightarrow Y \times_S Y$ this implies that $f = g = \tilde{F} \circ \iota^{-1}$. \square

Lemma 8.13. Let X be a scheme and consider an exact sequence of quasi-coherent \mathcal{O}_X -modules,

$$0 \longrightarrow \mathcal{I} \longrightarrow \mathcal{O}_X \longrightarrow \mathcal{A} \longrightarrow 0$$

and \mathcal{A} is a sheaf of \mathcal{O}_X -algebra. Suppose that $\mathcal{F}_x \neq 0$ for each $x \in X$. Then $\mathcal{I} \hookrightarrow \mathcal{N}$ where \mathcal{N} is the sheaf of nilpotent.

Proof. Take an affine open $U = \text{Spec}(R) \subset X$ such that $\mathcal{A}|_U = \widetilde{A}$. Then we have an surjection of rings $R \twoheadrightarrow A$ giving $R/I = A$ for $I = \ker(R \rightarrow A)$. Now, for each $\mathfrak{p} \in \text{Spec}(R)$ we know $R_{\mathfrak{p}} = \mathcal{O}_{X,\mathfrak{p}} \neq 0$. However, if $\mathfrak{p} \not\supset I$ then $(R/I)_{\mathfrak{p}} = A_{\mathfrak{p}} = 0$ so we must have $\mathfrak{p} \supset I$ for all $\mathfrak{p} \in \text{Spec}(R)$ i.e. $I \subset \text{nilrad}(R)$. Therefore, $\mathcal{I}|_U \hookrightarrow \mathcal{N}|_U$ for any affine open $U \subset X$ showing that \mathcal{I} is comprised of nilpotents. \square

Corollary 8.14. If X is reduced and $\iota : Z \hookrightarrow X$ is a surjective closed immersion then $\iota : Z \xrightarrow{\sim} X$ is an isomorphism.

Proof. Since $\iota : Z \hookrightarrow X$ is a homeomorphism onto its image X it suffices to show that the map of sheaves $\iota^\# : \mathcal{O}_X \rightarrow \iota_*\mathcal{O}_Z$ is an isomorphism. Since $\iota : Z \rightarrow X$ is a closed immersion $\iota^\# : \mathcal{O}_X \rightarrow \iota_*\mathcal{O}_Z$ is a surjection and \mathcal{O}_Z is a quasi-coherent sheaf of \mathcal{O}_X -algebras giving an exact sequence,

$$0 \longrightarrow \mathcal{I} \longrightarrow \mathcal{O}_X \longrightarrow \iota_* \mathcal{O}_Z \longrightarrow 0$$

Furthermore,

$$\text{Supp}_{\mathcal{O}_X}(\iota_* \mathcal{O}_Z) = \text{Im}(\iota) = X$$

since $(\iota_* \mathcal{O}_Z)_x = \mathcal{O}_{Z,x}$ when $x \in \text{Im}(\iota)$ (and zero elsewhere). by the above, $\mathcal{I} \hookrightarrow \mathcal{N} = 0$ since X is reduced to $\iota^\# : \mathcal{O}_X \rightarrow \iota_* \mathcal{O}_Z$ is an isomorphism. \square

Lemma 8.15. A rational S -map $f : X \dashrightarrow Y$ with X reduced and $Y \rightarrow S$ separated is equivalent to a morphism $f : \text{Dom}(f) \rightarrow Y$.

Proof. For any (U, f_U) and (V, f_V) representing f there must be a dense (in X) open $W \subset U \cap V$ on which $f_U|_W = f_V|_W$ and thus $f_U|_{U \cap V} = f_V|_{U \cap V}$ since $f_U, f_V : U \cap V \rightarrow Y$ are morphisms from reduced to irreducible schemes. Now $\text{Dom}(f)$ has an open cover (U_i, f_i) for which $f_i|_{U_i \cap U_j} = f_j|_{U_i \cap U_j}$ so these morphisms glue to give $f : \text{Dom}(f) \rightarrow Y$ ($\text{Hom}_S(-, Y)$ is a sheaf on the Zariski site). \square

8.3 Extending Rational Maps

Lemma 8.16. Regular local rings of dimension 1 exactly correspond to DVRs.

Proof. Any DVR R has a uniformizer $\varpi \in R$ then $\dim R = 1$ and $\mathfrak{m}/\mathfrak{m}^2 = (\varpi)/(\varpi^2) = \varpi\kappa$ which also has $\dim_\kappa(\mathfrak{m}/\mathfrak{m}^2) = 1$ so R is regular.

Conversely, if R is a regular local ring of dimension $\dim R = 1$ then, by regularity, R is a normal Noetherian domain so by $\dim R = 1$ then R is Dedekind but also local and thus is a DVR. \square

Proposition 8.17. Let X be a Noetherian S -scheme and $Z \subset X$ a closed irreducible codimension 1 generically nonsingular subset (with generic point $\eta \in Z$ such that $\mathcal{O}_{X,\eta}$ is regular). Let $f : X \dashrightarrow Y$ be a rational map with Y proper over S . Then $Z \cap \text{Dom}(f)$ is a dense open of Z .

Proof. Choose some representative (U, f_U) for $f : X \dashrightarrow Y$. Note that $\mathcal{O}_{X,\eta}$ is a regular dimension one (see Lemma 8.23) ring and thus a DVR. Consider the generic point $\xi \in X$ of X then, by localizing, we get an inclusion of the generic point $\text{Spec}(\mathcal{O}_{X,\xi}) \rightarrow \text{Spec}(\mathcal{O}_{X,\eta}) \rightarrow X$ and $\mathcal{O}_{X,\xi} = K(X) = \text{Frac}(\mathcal{O}_{X,\eta})$. Furthermore, the inclusion of the generic point gives $\text{Spec}(K(X)) \rightarrow U \xrightarrow{f_U} Y$ and thus we get a diagram,

$$\begin{array}{ccc} \text{Spec}(K(X)) & \xrightarrow{\quad} & Y \\ \downarrow & \nearrow \ell & \downarrow \\ \text{Spec}(\mathcal{O}_{X,\eta}) & \xrightarrow{\quad} & \text{Spec}(k) \end{array}$$

and a lift $\text{Spec}(\mathcal{O}_{X,\eta}) \rightarrow Y$ by the valuative criterion for properness applied to $Y \rightarrow \text{Spec}(k)$ since $\mathcal{O}_{X,\eta}$ is a DVR. Choose an affine open $\text{Spec}(R) \subset Y$ containing the image of $\text{Spec}(\mathcal{O}_{X,\eta}) \rightarrow Y$ (i.e. choose a neighborhood of the image of η which automatically contains $f(\xi)$ since the map factors $\text{Spec}(\mathcal{O}_{X,\eta}) \rightarrow \text{Spec}(\mathcal{O}_{Y,f(\eta)}) \rightarrow \text{Spec}(R) \rightarrow Y$) and let $\eta \in V = \text{Spec}(A) \subset X$ be an affine open neighborhood of ξ mapping onto $\text{Spec}(R)$. By Lemma 8.27, since $\mathcal{O}_{X,\eta}$ is a domain, we may shrink V so that A is a domain. Since X is irreducible $U \cap V$ is a dense open. Note that if $\eta \in U$ then $\eta \in \text{Dom}(f)$ and thus $Z \cap \text{Dom}(f)$ is a nonempty open of the irreducible space Z and therefore a dense open so we are done. Otherwise, let $\mathfrak{p} \in \text{Spec}(A)$ correspond to $\eta \in Z$ then $A_{\mathfrak{p}} = \mathcal{O}_{X,\eta}$ is a DVR. Take some principal affine open $D(f) \subset U \cap V$ for $f \in A$ so $f \in \mathfrak{p}$ since $\mathfrak{p} \notin D(f) \subset U \cap V$. Since $A_{\mathfrak{p}}$ is a DVR we may choose a uniformizer $\varpi \in \mathfrak{p}$ so the map $A \rightarrow \mathfrak{p}$

via $1 \mapsto \varpi$ is an isomorphism when localized at \mathfrak{p} . Since A is Noetherian both are f.g. A -modules so there must be some $s \in A \setminus \mathfrak{p}$ such that $A_s \rightarrow \mathfrak{p}_s$ is an isomorphism. Replacing A by A_s we may assume $\mathfrak{p} = (\varpi) \subset A$ is principal. Since $f \in \mathfrak{p}$ we can write $f = t\varpi^k$ for some $a \in A \setminus \mathfrak{p}$ (see Lemma 8.21). Then consider $\tilde{V} = \text{Spec}(A_t)$. Since $t \notin \mathfrak{p}$ then $\eta \in \tilde{V}$ and since $f = t\varpi^k$ we have $D(f) \subset D(t) = \tilde{V}$. Now we get the following diagram,

$$\begin{array}{ccc}
 & & \text{Spec}(R) \\
 & \nearrow \ell & \\
 \text{Spec}(A_{\mathfrak{p}}) & \longrightarrow & \text{Spec}(A_t) \\
 \uparrow & & \uparrow \\
 \text{Spec}(\text{Frac}(A)) & \longrightarrow & \text{Spec}(A_f)
 \end{array}$$

$\text{Spec}(A_t) \xrightarrow{f_V} \text{Spec}(R)$ (dashed arrow)
 $\text{Spec}(A_f) \xrightarrow{f_U} \text{Spec}(R)$ (curved arrow)

I claim the square is a pushout in the category of affine schemes because maps $R \rightarrow A_{\mathfrak{p}}$ and $R \rightarrow A_f$ which agree under the inclusion to $\text{Frac}(A)$ gives a map $R \rightarrow A_{\mathfrak{p}} \cap A_f \subset \text{Frac}(A)$. However, consider,

$$x \in A_{\mathfrak{p}} \cap A_t \implies x = \frac{u\varpi^r}{s} = \frac{a}{f^n}$$

for $u, s, t \in A \setminus \mathfrak{p}$ and $a \in A$. Thus we get,

$$ut^n\varpi^{r+nk} = sa$$

so $a \in \mathfrak{p}^{r+nk} \setminus \mathfrak{p}^{r+nk+1}$ ($s \notin \mathfrak{p}$ which is prime) and thus $a = u'\varpi^{r+nk}$ for $u' \in A \setminus \mathfrak{p}$. Therefore,

$$x = \frac{u'\varpi^{r+nk}}{t^n\varpi^{nk}} = \frac{u'\varpi^r}{t^n} \in A_t$$

Thus, $A_{\mathfrak{p}} \cap A_f \subset A_t$ so we get a map $R \rightarrow A_t$. Therefore we get a map $f_{\tilde{V}} : \tilde{V} \rightarrow Y$ such that $(f|_{\tilde{V}})|_{D(f)} = (f_U)|_{D(f)}$ which implies that $\eta \in \tilde{V} \subset \text{Dom}(f)$ so $Z \cap \text{Dom}(f)$ is a dense open of Z . \square

Proposition 8.18. Let $C \rightarrow S$ be a proper regular Noetherian scheme with $\dim C = 1$ and $f : C \dashrightarrow Y$ a rational S -map with $Y \rightarrow S$ proper. Then f extends uniquely to a morphism $f : C \rightarrow Y$.

Proof. For any point $x \notin \text{Dom}(f)$ let $Z = \overline{\{x\}} \subset D$ for $D = C \setminus \text{Dom}(f)$. Since $\text{Dom}(f)$ is a dense open, by lemma 8.22, we have $\text{codim}(Z, C) \geq \text{codim}(D, C) \geq 1$ but $\dim C = 1$ so $\text{codim}(Z, C) = 1$. Furthermore, since C is regular $\mathcal{O}_{C,x}$ is regular and thus, by the previous proposition, $Z \cap \text{Dom}(f)$ is a dense open and in particular $x \in \text{Dom}(f)$ meaning that $\text{Dom}(f) = C$ so we get a morphism $C \rightarrow Y$. This is unique because C is reduced (it is regular) and Y is separated (it is proper over S) so morphisms $C \rightarrow Y$ are uniquely determined on a dense open which any representative for $f : C \dashrightarrow Y$ is defined on. \square

Corollary 8.19. Rational maps between normal proper curves are morphisms.

Corollary 8.20. Birational maps between normal proper curves are isomorphisms.

Proof. Let $f : C_1 \dashrightarrow C_2$ and $g : C_2 \dashrightarrow C_1$ be birational inverses of smooth proper curves. Then we know that these extend to morphisms $f : C_1 \rightarrow C_2$ and $g : C_2 \rightarrow C_1$. Furthermore, the maps $g \circ f : C_1 \rightarrow C_1$ must extend the identity on some dense open. However, since curves are separated and reduced there is a unique extension of this map so $g \circ f = \text{id}_{C_1}$ and likewise $f \circ g = \text{id}_{C_2}$. \square

Theorem 8.1. If k is perfect then there exists a unique normal curve in each birational equivalence class of curves.

Proof. It suffices to show existence. Given a curve X , we consider the projective closure $X \hookrightarrow \overline{X}$ which is birational and $\overline{X} \rightarrow \text{Spec}(k)$ is proper. Then take the normalization $\overline{X}^\nu \rightarrow \overline{X}$ which remains proper over $\text{Spec}(k)$ and is birational. Then \overline{X}^ν is regular and thus smooth over k since k is perfect and $\overline{X}^\nu \rightarrow X$ is birational. \square

8.4 Lemmas

Lemma 8.21. Let A be a Noetherian domain and $\mathfrak{p} = (\varpi)$ a principal prime. Then any $f \in \mathfrak{p}$ can be written as $f = t\varpi^k$ for $f \in A \setminus \mathfrak{p}$.

Proof. From Krull intersection,

$$\bigcap_{n \geq 0} \mathfrak{p}^n = (0)$$

so there is some n such that $f \in \mathfrak{p}^n \setminus \mathfrak{p}^{n+1}$. Thus $f = t\varpi^n$ for some $f \in A$ but if $t \in \mathfrak{p}$ then $f \in \mathfrak{p}^{n+1}$ so the result follows. \square

Lemma 8.22. Consider a closed subset $Y \subset X$ and an open $U \subset X$ with $U \cap Z \neq \emptyset$. Then $\text{codim}(Y, X) = \text{codim}(Y \cap U, U)$.

Proof. Consider a chain of irreducible $Z_i \supsetneq Z_{i+1}$ with $Z_0 \subset Y$. I claim that $Z_i \mapsto Z_i \cap U$ and $Z_i \mapsto \overline{Z_i}$ are inverse functions giving a bijection between closed irreducible chains in X with final terms contained in Y and closed irreducible chains in U with final term contained in $Y \cap U$. Note, if $Z_i \subset Y \cap U$ then $\overline{Z_i} \subset Y$ since Y is closed in X .

First, $\overline{Z_i \cap U} \subset Z_i$ and is closed in X . Then $\overline{Z_i \cap U} \cup U^c \supset Z_i$ so because Z_i is irreducible $\overline{Z_i \cap U} = Z_i$ since by assumption $Z_i \not\subset U^c$. Conversely, if $Z_i \subset U$ is a closed irreducible subset then $\overline{Z_i}$ is closed and irreducible in X and $Z_i \subset \overline{Z_i} \cap U$ but $Z_i = C \cap U$ for closed $C \subset X$ so $Z_i \subset C$ and thus $\overline{Z_i} \subset C$ so $\overline{Z_i} \cap U \subset C \cap U = Z_i$ meaning $Z_i = \overline{Z_i} \cap U$. Thus we have shown these operations are inverse to each other.

Finally, if $Z_i \cap U = Z_{i+1} \cap U$ then $\overline{Z_i \cap U} = \overline{Z_{i+1} \cap U}$ so $Z_i = Z_{i+1}$ so the chain does not degenerate. Likewise, if $\overline{Z_i} = \overline{Z_{i+1}}$ then $\overline{Z_i} \cap U = \overline{Z_{i+1}} \cap U$ so $Z_i = Z_{i+1}$. Therefore, we get a length-preserving bijection between the chains defining $\text{codim}(Y, X)$ and $\text{codim}(Y \cap U, U)$. \square

Lemma 8.23. Let $Z \subset X$ be a closed irreducible subset with generic point $\eta \in Z$. Then $\text{codim}(Z, X) = \dim \mathcal{O}_{X, \eta}$.

Proof. Take affine open neighborhood $\eta \in U = \text{Spec}(A) \subset X$. Then for $\mathfrak{p} \in \text{Spec}(A)$ corresponding to η we get $A_{\mathfrak{p}} = \mathcal{O}_{X, \eta}$. However, $\text{codim}(Z, X) = \text{codim}(Z \cap U, U)$ and $Z \cap U = \overline{\{\mathfrak{p}\}} = V(\mathfrak{p})$. Therefore,

$$\text{codim}(Z, X) = \text{codim}(Z \cap U, U) = \text{ht}(\mathfrak{p}) = \dim A_{\mathfrak{p}} = \dim \mathcal{O}_{X, \eta}$$

\square

Lemma 8.24. Let X be a Noetherian scheme then the nonreduced locus,

$$Z = \{x \in X \mid \text{nilrad}(\mathcal{O}_{X,x}) \neq 0\}$$

is closed.

Proof. The subsheaf $\mathcal{N} \subset \mathcal{O}_X$ is coherent since X is Noetherian. Thus $Z = \text{Supp}_{\mathcal{O}_X}(\mathcal{N})$ is closed and $\mathcal{N}_x = \text{nilrad}(\mathcal{O}_{X,x})$. Locally, on $U = \text{Spec}(A)$ we have $\mathcal{N}|_U = \widetilde{\text{nilrad}(A)}$ and $\text{nilrad}(A)$ is a f.g. A -module since A is Noetherian so,

$$\text{Supp}_{\mathcal{O}_X}(\mathcal{N}) \cap U = \text{Supp}_A(\text{nilrad}(A)) = V(\text{Ann}_A(\text{nilrad}(A)))$$

is closed in $\text{Spec}(A)$. □

Lemma 8.25. Let X be a Noetherian scheme then X has finitely many irreducible components.

Proof. First let $X = \text{Spec}(A)$ for a Noetherian ring A . Then the irreducible components of A correspond to minimal primes $\mathfrak{p} \in \text{Spec}(A)$. Then $\dim A_{\mathfrak{p}} = 0$ and $A_{\mathfrak{p}}$ is Noetherian so $A_{\mathfrak{p}}$ is Artinian. $A_{\mathfrak{p}}$ must have some associated prime so $\text{Ass}_{A_{\mathfrak{p}}}(A_{\mathfrak{p}}) = \{\mathfrak{p}A_{\mathfrak{p}}\}$. By Tag 05BZ, then $\text{Ass}_A(A) \cap \text{Spec}(A_{\mathfrak{p}}) = \text{Ass}_{A_{\mathfrak{p}}}(A_{\mathfrak{p}}) = \{\mathfrak{p}\}$ so every minimal prime is an associated prime. However, for A Noetherian then A admits a finite composition series so there are finitely many associated primes.

Now let X be a Noetherian scheme. For any affine open $U \subset X$ we have shown that U has finitely many irreducible components. However, since X is quasi-compact there is a finite cover of affine opens and thus X must have finitely many irreducible components. □

Lemma 8.26. Let X be a Noetherian scheme and Y is the complement of some dense open U . Then $\text{codim}(Y, X) \geq 1$.

Proof. It suffices to show that Y does not contain any irreducible component since then any irreducible contained in Y cannot be maximal. Since X is Noetherian, it has finitely many irreducible components Z_i . Then if $Z_j \subset Y$ for some i we would have $Z_i \cap U = \emptyset$ but then,

$$U = \bigcup_{i \neq j} Z_i$$

which is closed so $\overline{U} \subsetneq X$ contradicting our assumption that U is dense. □

Lemma 8.27. Let X be a Noetherian scheme and $x \in X$ such that $\mathcal{O}_{X,x}$ is a domain. Then there is an affine open neighborhood $x \in U \subset X$ with $U = \text{Spec}(A)$ and A is a domain.

Proof. Take any affine open neighborhood $x \in U \subset X$ with $U = \text{Spec}(A)$ and $\mathfrak{p} \in \text{Spec}(A)$ corresponding to x . Then $A_{\mathfrak{p}} = \mathcal{O}_{X,x}$ is a domain. Since X is Noetherian then A is Noetherian so it has finitely many minimal primes \mathfrak{p}_i (corresponding to the generic points of irreducible components of U) with $\mathfrak{p}_0 \subset \mathfrak{p}$. Since $A_{\mathfrak{p}}$ is a domain, it has a unique minimal prime and thus \mathfrak{p}_0 is the only minimal prime contained in \mathfrak{p} (geometrically $A_{\mathfrak{p}}$ being a domain corresponds to the fact that \mathfrak{p} is the generic point of a generically reduced irreducible subset which lies in only one irreducible component)

Now for any $i \neq 0$ take $f_i \in \mathfrak{p} \setminus \mathfrak{p}_0$. This is always possible else $\mathfrak{p} \subset \mathfrak{p}_0$ contradicting the minimality

of \mathfrak{p}_0 . If $f \notin \mathfrak{q}$ then $\mathfrak{q} \not\supset \mathfrak{p}_i$ for any $i \neq 0$ so $\mathfrak{q} \supset \mathfrak{p}_0$ since it must lie above some minimal prime. Thus $\text{nilrad}(A_f) = \mathfrak{p}_0 A_f$ is prime and $f \notin \mathfrak{p}$ since else $\mathfrak{p} \supset \mathfrak{p}_1 \cap \dots \cap \mathfrak{p}_n$ which is impossible since $\mathfrak{p} \not\supset \mathfrak{p}_i$ for any i . Now we know that $\text{nilrad}(A_{\mathfrak{p}}) = 0$ and A_f is Noetherian so $\text{nilrad}(A_{\mathfrak{p}})$ is finitely generated. Thus, there is some $g \notin \mathfrak{p}$ such that $\text{nilrad}(A_{fg}) = (\text{nilrad}(A_f))_g = 0$. Thus A_{fg} is a domain since $\text{nilrad}(A_{fg}) = (0)$ and is prime and $\mathfrak{p} \in A_{fg}$ because $fg \notin \mathfrak{p}$. Therefore, $x \in \text{Spec}(A_{fg}) \subset U$ is an affine open satisfying the requirements. \square

Remark. This does not imply that X is integral if $\mathcal{O}_{X,x}$ is a domain for each $x \in X$ (which is false, consider $\text{Spec}(k \times k)$) because it only shows there is an integral cover of X not that $\mathcal{O}_X(U)$ is a domain for each U .

Example 8.28. Let $X = \text{Spec}(k[x, y]/(xy, y^2))$. Then for the bad point $\mathfrak{p} = (x, y)$ we have $\text{nilrad}(\mathcal{O}_{X,\mathfrak{p}}) = (y)$. Away from the bad point, say $\mathfrak{p} = (x-1, y)$ we have, $\mathcal{O}_{X,\mathfrak{p}} = \text{Spec}(k[x]_{(x-1)})$ so $\text{nilrad}(\mathcal{O}_{X,\mathfrak{p}}) = (0)$. Furthermore, at the generic point $\mathfrak{p} = (y)$, we have, $\mathcal{O}_{X,\mathfrak{p}} = \text{Spec}(k(x))$ so $\text{nilrad}(\mathcal{O}_{X,\mathfrak{p}}) = (0)$.

Example 8.29. Consider $X = \text{Spec}(k[x, y, z]/(yz))$ which is the union of the x - y and x - z planes. Consider the generic point of the z -axis $\mathfrak{p} = (x, y)$ then $\mathcal{O}_{X,\mathfrak{p}} = \text{Spec}(k[x, z]_{(x)})$ is a domain since the z -axis only lies in one irreducible component. However, at the generic point of the x -axis, $\mathfrak{p} = (y, z)$ we get $\mathcal{O}_{X,\mathfrak{p}} = \text{Spec}((k[x, y, z]/(yz))_{(y,z)})$ has zero divisors $yz = 0$ so is not a domain since the x -axis lives in two irreducible components.

8.5 Reflexive Sheaves (WIP)

Definition 8.30. Recall the dual of a \mathcal{O}_X module \mathcal{F} is the sheaf $\mathcal{F}^\vee = \mathcal{H}om_{\mathcal{O}_X}(\mathcal{F}, \mathcal{O}_X)$. We say that a coherent \mathcal{O}_X -module \mathcal{F} is *reflexive* if the natural map $\mathcal{F} \rightarrow \mathcal{F}^{\vee\vee}$ is an isomorphism.

Lemma 8.31. Let X be an integral locally Noetherian scheme and \mathcal{F}, \mathcal{G} be coherent \mathcal{O}_X -modules. If \mathcal{G} is reflexive then $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{F}, \mathcal{G})$ is reflexive.

Tag. 0AY4. \square

In particular, since \mathcal{O}_X is clearly reflexive, this lemma shows that for any coherent \mathcal{O}_X -module then \mathcal{F}^\vee is a reflexive coherent sheaf. We say the map $\mathcal{F} \rightarrow \mathcal{F}^{\vee\vee}$ gives the reflexive hull $\mathcal{F}^{\vee\vee}$ of \mathcal{F} .

Definition 8.32. Let \mathcal{R} be the full subcategory $\mathcal{Coh}(\mathcal{O}_X)$ of coherent reflexive \mathcal{O}_X -modules. \mathcal{R} is an additive category and in fact has all kernels and cokernels defined by taking reflexive hulls of the sheaf kernel and cokernel. Furthermore, \mathcal{R} inherits a monoidal structure from the tensor product defined using the reflexive hull as follows,

$$\mathcal{F} \otimes_{\mathcal{R}} \mathcal{G} = (\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{G})^{\vee\vee}$$

Finally, we define $\text{RPic}(X)$ to be group of constant rank one reflexives induced by the monoidal structure on \mathcal{R} . Explicitly, $\text{RPic}(X)$ is the group of isomorphism classes of constant rank one reflexive coherent \mathcal{O}_X -modules with multiplication $(\mathcal{F}, \mathcal{G}) \mapsto (\mathcal{F} \otimes_{\mathcal{O}_X} \mathcal{G})^{\vee\vee}$ and inverse $\mathcal{F} \mapsto \mathcal{F}^\vee$.

The importance of reflexive sheaves derives from their correspondence to Weil divisors. Here we let X be a normal integral separated Noetherian scheme.

Proposition 8.33. If D is a Weil divisor then $\mathcal{O}_X(D)$ is reflexive of constant rank one.

Proof. (CITE OR DO). □

Theorem 8.34. Let X be a normal integral separated Noetherian scheme. There is an isomorphism of groups $\text{Cl}(X) \xrightarrow{\sim} \text{RPic}(X)$ defined by $D \mapsto \mathcal{O}_X(D)$.

Proof. (DO OR CITE) □

We summarize the important results as follows.

Theorem 8.35. Let X be a Noetherian normal integral scheme. Then for any Weil divisors D, E ,

- (a). $\mathcal{O}_X(D + E) = (\mathcal{O}_X(D) \otimes_{\mathcal{O}_X} \mathcal{O}_X(E))^{\vee\vee}$
- (b). $\mathcal{O}_X(-D) = \mathcal{O}_X(D)^\vee$
- (c). $\mathcal{H}om_{\mathcal{O}_X}(\mathcal{O}_X(D), \mathcal{O}_X(E)) = \mathcal{O}_X(E - D)$
- (d). if E is Cartier then $\mathcal{O}_X(D + E) = \mathcal{O}_X(D) \otimes_{\mathcal{O}_X} \mathcal{O}_X(E)$

Proof. (DO OR CITE) □

Finally, we have a result which controls when the dualizing sheaf can be expressed in terms of a divisor.

Proposition 8.36. Let X be a projective variety over k . Then,

- (a). if X is normal then its dualizing sheaf ω_X is reflexive of rank 1 and thus X admits a canonical divisor K_X s.t. $\omega_X = \mathcal{O}_X(K_X)$
- (b). if X is Gorenstein then ω_X is an invertible module so K_X is Cartier.

Proof. (FIND CITATION OR DO). □
