

# 1 Mar. 30

*Remark.* Here is a reason that a  $-1$ -category should be the initial (empty) category or the terminal category (single object and single morphism). We want the Hom spaces of a  $0$ -category (a set) to be  $-1$ -categories but these are singletons or empty. Therefore, we can say that a  $-1$ -sheaf ( $-2$ -stack) should be a function because its a category fibered over  $X$  in  $-1$ -categories so just a single element over open compatibly with restriction.

Given a (pre)sheaf on a topological space  $X$  we can “glue the fibers together” to get a fibered category over  $\text{Open}(U)$  where the fibers are the sets  $\mathcal{F}(U)$  over some open. The morphisms in this category are exactly  $f|_U \rightarrow f$  where the morphism represents the restriction of the function  $f$  over  $U \hookrightarrow V$ . To make this a sheaf we need axioms involving the topology.

We do the same thing for stacks.

**Definition 1.0.1.** A 2-presheaf over a topological space  $X$  is a functor  $f : \mathcal{C} \rightarrow \text{Open}(X)$  such that

- (a) pullbacks exist
- (b) every morphism in  $\mathcal{C}$  is a pullback

*Remark.* Some exercises:

- (a) the fibers of a 2-presheaf are groupoids.

**Definition 1.0.2.** Let  $\mathcal{C}$  be a 2-presheaf then  $\mathcal{C}$  is a stack if

- (a) for  $a, b \in \mathcal{C}(U)$  the functor  $\text{Isom}(a, b)$  is a sheaf on  $U$
- (b) objects glue.

**Definition 1.0.3.** A category of geometric spaces is a category  $\mathcal{G}$  such that there is a distinguished class of “open immersions” which is

- (a) closed under composition
- (b) local in nature
- (c) preserved by pullbacks (fibered products)

**Proposition 1.0.4** (Yonega). Consider the category  $\text{PSh}_{\mathcal{C}}$  which is the contravariant functors from  $\mathcal{C}$  to  $\text{Set}$ . Then  $X \mapsto h^X = \text{Hom}_{\mathcal{C}}(-, X)$  gives a fully faithfully embedding  $\mathcal{C} \hookrightarrow \text{PSh}_{\mathcal{C}}$ .

## 2 Geometry on PSh

What is a vectorbundle on a presheaf? If we are going to give it geometry we should know an answer to this question.

Example, the Hodge bundle. For any  $S \rightarrow \mathcal{M}_g$  there is a family of curves  $\pi : \mathcal{C} \rightarrow S$  and thus we get the Hodge bundle  $\pi_*\Omega_{\mathcal{C}/S}$  which is a rank  $g$  vector bundle on  $S$ . These vector bundles are compatible (by cohomology and base change) with pullbacks  $S' \rightarrow S \rightarrow \mathcal{M}_g$ .

We call this data a vector bundle on  $\mathcal{M}_g$ .

**Definition 2.0.1.** A vector bundle  $\mathcal{E}$  on  $\mathcal{F} \in \text{PSh}_{\mathcal{G}}$  is a vector bundle  $\mathcal{E}(S)$  on each  $S \in \mathcal{G}$  along with isomorphisms (DO THIS)

**Exercise 2.0.2.** Let  $\mathcal{G}$  be the category of open balls in  $\mathbb{C}^n$  and holomorphic maps between them. Then  $\text{Man}_{\mathbb{C}} \rightarrow \text{PSh}_{\mathcal{G}}$  is a fully faithful embedding.

---

## 2.1 Fiber Products

$\mathcal{G}$  may not have fiber products because. For example if  $\mathcal{G}$  is the category of smooth manifolds and smooth maps then fiber products of non submersions is not a smooth manifold.

However,  $\text{PSh}_{\mathcal{G}}$  does have fiber products. Indeed we construct fiber products point-wise.

**Exercise 2.1.1.** Any fiber product in  $\mathcal{G}$  agrees with the corresponding fiber product in  $\text{PSh}_{\mathcal{G}}$  (the Yoneda embedding preserves fiber products).

---

The Yoneda functor preserves fiber products basically by definition because

$$h^{A \times_B C}(X) = \text{Hom}_{\mathcal{G}}(X, A \times_B C) = \text{Hom}_{\mathcal{G}}(X, A) \times_{\text{Hom}_{\mathcal{G}}(X, B)} \text{Hom}_{\mathcal{G}}(X, C)$$

**Definition 2.1.2.** A morphism  $f : F \rightarrow G$  in  $\text{PSh}_{\mathcal{G}}$  is representable when for any map  $S \rightarrow G$  from  $S \in \mathcal{G}$  then  $F \times_G S$  is representable.

*Remark.* If  $\mathcal{G}$  has fiber products then every morphism between representable functors is representable.

**Exercise 2.1.3.** Representable morphisms are preserved by base change.

---

**Definition 2.1.4.** Given a property  $\mathcal{P}$  of morphisms in  $\mathcal{G}$ . Then we say a representable morphism  $f : F \rightarrow G$  in  $\text{PSh}_{\mathcal{G}}$  has property  $\mathcal{P}$  if for every  $S \rightarrow G$  with  $S \in \mathcal{G}$  the morphism  $F \times_G S \rightarrow S$  (which is a  $\mathcal{G}$ -morphism) has property  $\mathcal{P}$ .

*Remark.* For this to make sense, we need  $\mathcal{P}$  to be a property preserved under base change so that  $X \rightarrow Y$  has property  $\mathcal{P}$  if and only if  $X_{Y'} \rightarrow Y'$  has property  $\mathcal{P}$ .

**Definition 2.1.5.** We can now define an open cover in  $\text{PSh}_{\mathcal{G}}$ . A representable morphism is open in the above sense.

## 3 April 4

*Remark.* Notice that every representable presheaf on  $\mathcal{G}$  is a sheaf when restricted to each object  $X \in \mathcal{G}$ .

**Definition 3.0.1.** A presheaf  $F \in \text{PSh}_{\mathcal{G}}$  is a *sheaf* if for each  $X \in \mathcal{G}$  the presheaf  $X|_{\mathcal{G}}$  (restriction to the open subsets of  $\mathcal{G}$ ) is a sheaf.

*Remark.* This will be a sheaf for the topology on  $\mathcal{G}$  induced by open embeddings.

**Definition 3.0.2.** Let  $\mathcal{G}$  be a category (not necessarily with fiber products). A topology on  $\mathcal{G}$  is a connection of morphisms  $\mathcal{G}^{\circ} \subset \mathcal{G}$  (the “open immersions”) satisfying the following properties:

- (a) and isomorphism  $f : X \rightarrow Y$  is in  $\mathcal{G}^\circ$  (for example  $\text{id}_X$  because  $\mathcal{G}^\circ$  is a subcategory)
- (b) openness is preserved under composition ( $\mathcal{G}$  is a subcategory)
- (c) pullbacks of morphisms in  $\mathcal{G}^\circ$  by morphisms in  $\mathcal{G}$  exist and are in  $\mathcal{G}^\circ$ .
- (d) the fiber product of  $U_1 \rightarrow X$  and  $U_2 \rightarrow X$  gives  $U_1 \times_X U_2 \rightarrow X$  is open (this is implied by composition and preservation under fiber products).

Along with the data of distinguished collections of morphisms in  $\mathcal{G}^\circ$  called covering families such that

- (a) every isomorphism  $f : X \rightarrow Y$  is a covering family
- (b) given a covering on  $Y$  and a morphism  $f : X \rightarrow Y$  then the base change is a cover of  $X$
- (c) a cover of a cover is a cover meaning if  $\{X_\alpha \rightarrow X\}$  is a covering family and  $\{X_{\beta\alpha} \rightarrow X_\alpha\}$  are covering families then  $\{X_{\beta\alpha} \rightarrow X\}$  is a covering family.

**Definition 3.0.3.** The category of sheaves  $\mathfrak{Sh}_{\mathcal{G}} \subset \text{PSh}_{\mathcal{G}}$  is the full subcategory of objects “determined locally on covers” i.e. satisfying the usual sheaf axiom.

**Exercise 3.0.4.**  $\mathfrak{Sh}_{\mathcal{G}}$  has all fiber products and they agree with fiber products in  $\mathcal{G}$  (when they exist) and an in  $\text{PSh}_{\mathcal{G}}$  under the fully faithfully embeddings,

$$\mathcal{G} \hookrightarrow \mathfrak{Sh}_{\mathcal{G}} \hookrightarrow \text{PSh}_{\mathcal{G}}$$

**Definition 3.0.5.** If  $X \in \mathcal{G}$  define  $\mathcal{G}_X$  the slice category of morphisms  $f : Y \rightarrow X$ .

**Definition 3.0.6.** A sheaf  $F \in \mathfrak{Sh}_{\mathcal{G}}$  is *locally representable* if there is an open cover by representable sheaves. Explicitly there are representable sheaves and representable morphisms  $U_i \rightarrow F$  such that for every such diagram,

$$\begin{array}{ccc} X_i & \longrightarrow & X \\ \downarrow & \lrcorner & \downarrow \\ U_i & \longrightarrow & F \end{array}$$

for  $X \in \mathcal{G}$  we have  $\{X_i \rightarrow X\}$  is a covering family in  $\mathcal{G}$ .

*Remark.* Applying this construction we get:

- (a) for affine schemes and open immersions get all schemes
- (b) for varieties and open immersions get pre-varieties (no separatedness or quasi-compactness)
- (c) for open balls in  $\mathcal{C}^n$  with open holomorphic embeddings get pre-manifolds (no Hausdorffness or second countability).

## 4 April 6

Reminder about  $\mathcal{G}$ : maybe it doesn't have fiber products (e.g. manifolds). We require our topology is *subcanonical* meaning for any  $Y \in \mathcal{G}$  the functor  $h^Y$  is a sheaf.

Our category  $\mathcal{G}$  is often a subcategory of locally ringed spaces. In most cases we can recover the sheaf of rings via maps to a ring object  $\mathbb{A}^1 \in \mathcal{G}$ .

**Exercise 4.0.1.**  $\text{LRep}_{\text{AffSch}} \subset \text{Sch}$ .

---

**Theorem 4.0.2.** If  $\mathcal{G}$  contains all fiber products (and a terminal object) then every  $M \in \text{LRep}_{\mathcal{G}}$  has  $\Delta : M \rightarrow M \times M$  representable.

*Remark.* In the example  $\mathcal{G} = \text{AffSch}$  we see that  $\mathbb{A}^2$  with the doubled origin is not in  $\text{LRep}_{\mathcal{G}}$  because its diagonal is not affine and hence not representable.

**Lemma 4.0.3.** If  $\mathcal{G}$  has products and fiber products. Then all maps  $X \rightarrow F$  for  $X \in \mathcal{G}$  and  $F \in \text{PSh}_{\mathcal{G}}$  are representable if and only if  $\Delta : F \rightarrow F \times F$  is representable.

*Proof.* First, assume that  $\Delta$  is representable. Then,

$$\begin{array}{ccc} X \times_F Y & \longrightarrow & Y \\ \downarrow & \lrcorner & \downarrow \\ X & \longrightarrow & F \end{array}$$

The following diagram is also cartesian,

$$\begin{array}{ccc} X \times_F Y & \longrightarrow & X \times Y \\ \downarrow & \lrcorner & \downarrow \\ F & \longrightarrow & F \times F \end{array}$$

and  $X \times Y \in \mathcal{G}$  so  $X \times_F Y \in \mathcal{G}$  proving the claim. Next, suppose that  $X \rightarrow F$  is always representable. For  $U \in \mathcal{G}$  and  $U \rightarrow F \times F$  we want to show that  $U \times_{F \times F} F \in \mathcal{G}$ .

$$\begin{array}{ccc} U \times_{F \times F} F & \longrightarrow & U \\ \downarrow & \lrcorner & \downarrow \\ U \times_F U & \longrightarrow & U \times U \\ \downarrow & \lrcorner & \downarrow \\ F & \longrightarrow & F \times F \end{array}$$

We see that  $U \times_F U$  is representable because  $U \rightarrow F$  is representable and thus the top square is all in  $\mathcal{G}$  and hence because  $\mathcal{G}$  has fiber products we conclude.  $\square$

*Remark.* Given a diagram,

$$\begin{array}{ccc} \text{Isom} & \longrightarrow & U \\ \downarrow & \lrcorner & \downarrow \\ F & \longrightarrow & F \times F \end{array}$$

then the pullback will classify isomorphisms between the objects over  $U$  represented by  $F$  under the two maps  $U \rightarrow F$ .

*Proof of Theorem.* We need to show that  $F \rightarrow F \times F$  is representable. By the lemma, it is equivalent to ask if for every diagram with  $X, Y \in \mathcal{G}$  we have,

$$\begin{array}{ccc} X \times_F Y & \longrightarrow & Y \\ \downarrow & & \downarrow \\ X & \longrightarrow & F \end{array}$$

we want  $X \times_F Y$  is representable. Choose a cover  $U_i \rightarrow F$  by representable  $U_i$ . Then we pullback to get  $\square$

## 4.1 Complex Analytic Spaces

## 4.2 Sheafification

## 5 April 8

Given the data  $U_i \in \mathcal{G}$  along with opens immersions  $U_{ij} \hookrightarrow U_i$  and  $U_{ij} \rightarrow U_j$  such that  $U_{ij} \times_{U_i} U_{ik} = U_{kj} \times_{U_j} U_{ik}$  MAKE THIS WORK!!!

Then we get that,

$$M^-(X) = \text{Hom}_{\mathcal{G}}(X, \coprod U_i) / \text{Hom}_{\mathcal{G}}(X, \coprod U_{ij})$$

automatically  $M^-(X) \in \text{PSh}_{\mathcal{G}}^+$ . This cannot be the right presheaf however, for example  $\text{id}_M$  doesn't make sense because we are not stratifying  $X$ . To do this we exactly take the sheafification. Therefore we define  $M = (M^-)^+$ .

The claim is that  $U_i \rightarrow M$  is open and make  $M$  be locally representable.

*Remark.* Suppose that  $\Delta : M \rightarrow M \times M$  is representable. Then for any cover  $U_i \rightarrow M$  is

## 6 April —

## 7 April 13

Question: given  $\pi : U \rightarrow X$  in  $\mathcal{G}$  does  $F$  satisfy the sheaf condition for  $\pi$  meaning is,

$$F(X) \longrightarrow F(U) \rightrightarrows F(U \times_X U)$$

**Theorem 7.0.1.** If there is  $s : X \rightarrow U$  such that  $\pi \circ s = \text{id}$  then any presheaf  $F$  satisfies the sheaf condition for  $\pi : U \rightarrow X$ .

*Proof.* We get maps  $\sigma_i : U \rightarrow U \times_X U$  given by  $(\sigma, \text{id})$  and  $(\text{id}, \sigma)$ . Now we get  $s^* \pi^* = \text{id}$  so we see that  $\pi^*$  is injective giving the first part. For gluing, given  $s \in F(U)$  such that  $\pi_1^* s = \pi_2^* s$ . Then take  $t = \sigma^* s$  and we need to show that  $\pi^* t = s$ . Now  $\pi_1 \circ \sigma_2 = \sigma \circ \pi$  and thus,

$$\pi^* \sigma^* s = \sigma_2^* \pi_1^* s = \sigma_2^* \pi_2^* s = s$$

because  $\pi_1^* s = \pi_2^* s$  and  $\pi_2 \circ \sigma_2 = \text{id}$ .  $\square$

**Corollary 7.0.2.** Suppose we have a diagram,

$$\begin{array}{ccc} V & \longrightarrow & U \\ & \searrow & \downarrow \\ & & X \end{array}$$

If  $F$  satisfies the sheaf condition for  $V \rightarrow X$  then it satisfies the sheaf condition for  $U \rightarrow X$ .

*Proof.* Consider,

$$\begin{array}{ccc} V \times_X U & \longrightarrow & U \\ \downarrow & \nearrow & \downarrow \\ V & \longrightarrow & X \end{array}$$

We know automatically that  $F$  satisfies the sheaf condition for  $V \times_X U \rightarrow V$  because there is a section  $V \rightarrow V \times_X U$ . By assumption  $F$  is a sheaf for  $V \rightarrow X$ .  $\square$

## 8 April 20

### 8.1 Quasi-Coherent Sheaves on Algebraic Spaces

For every  $\text{Spec}(A) \rightarrow X$  where  $X$  is an algebraic space, I want an  $A$ -module  $M$  such that for  $\text{Spec}(A') \rightarrow \text{Spec}(A)$  we have  $M'$  is the pullback of  $M$ .

**Proposition 8.1.1.** If  $\pi : X \rightarrow Y$  is a quasi-compact and quasi-separated morphism of algebraic spaces and  $\mathcal{F}$  is quasi-coherent then  $\pi_* \mathcal{F}$  is quasi-coherent.

### 8.2 Čech Cohomology

For the Zariski topology (and also other cohomology) on  $X$  an algebraic space with quasi-compact and affine diagonal then Čech cohomology works for quasi-coherent sheaves.

## 9 Example

Consider  $\mathcal{M}_3^a$  the moduli space of genus 3 curves with no nontrivial automorphisms over  $\mathbb{C}$ . Let  $\mathcal{G} = \mathbf{Sch}_{\mathbb{C}}$  then  $\mathcal{M}_3^a \in \mathbf{PSh}_{\mathcal{G}}$  is the functor,

$S \mapsto \{\pi : C \rightarrow S \text{ relative dim 1 smooth geometrically integral fibers of genus 3 with no automorphisms}\}$

Consider  $\pi_* \Omega_{C/S}$  is a rank 3 vector bundle (by cohomology and base change) and thus we get a closed embedding,

$$C \hookrightarrow \mathbb{P}_S(\pi_* \Omega_{C/S})$$

over  $S$ . These are all embedded as plane quartic curves. Quartic divisors are parametrized by  $\mathbb{P}^{14}$  there is an open  $U \subset \mathbb{P}^{14}$  where the associated plane quadric is a smooth irreducible curve. Then,

$$\mathcal{M}_3^a = U/\text{PGL}_3$$

To see this, consider,

$$\begin{array}{ccc}
B_U & \longrightarrow & U \\
\downarrow & \lrcorner & \downarrow \\
B & \longrightarrow & \mathcal{M}_3^a
\end{array}$$

Then  $B_U$  is exactly  $\text{Isom}(\mathbb{P}_B(\pi_*\Omega_{C/S}), \mathbb{P}_B^3)$  which is a Zariski  $\text{PGL}_3$ -torsor OR MAYBE where  $C^{\text{univ}} \rightarrow U$  is the universal curve over  $U$ . Maybe it's actually correct to take the  $\text{PGL}_3$ -torsor  $D$  over  $B$  of sections of  $\mathbb{P}_S(\pi_*\Omega_{C/S})$  and tak

Let's check this. The  $T$ -points  $T \rightarrow B_U$  are exactly given by the following data  $(a, b, \gamma)$  where  $a : T \rightarrow B$  and  $b : T \rightarrow U$  and an isomorphism  $\gamma : C_T \xrightarrow{\sim} C_T^{\text{univ}}$  which is the data of a map

$$T \rightarrow \text{Isom}_{B \times U}(C_{B \times U}, C_{B \times U}^{\text{univ}})$$

However, since  $C^{\text{text}} \rightarrow U$  is universal the maps  $b : T \rightarrow U$  are exactly classified by isomorphism classes  $[C_T]$  as closed subschemes since because these curves are canonically embedded, as  $C \hookrightarrow \mathbb{P}_B(\pi_*\Omega_{X/S})$  and  $C^{\text{univ}} \hookrightarrow \mathbb{P}_U^3$  the isomorphism  $C_T \xrightarrow{\sim} C_T^{\text{univ}}$  induces an isomorphism  $\mathbb{P}(\pi_*\Omega_{X/S}) \xrightarrow{\sim} \mathbb{P}^3$ . For a fixed such isomorphism there is a unique map  $T \rightarrow U$  defined by the image of  $C_T$  in  $\mathbb{P}^3$  therefore,

$$B_U = \text{Isom}_{B \times U}(C_{B \times U}, C_{B \times U}^{\text{univ}}) = \text{Isom}_B(\mathbb{P}_B(\pi_*\Omega_{X/S}), \mathbb{P}_B^3)$$

## 10 April 25

**Definition 10.0.1.** A *sieve* over  $X$  is a sub-presheaf of  $h_X$ .

**Example 10.0.2.**  $S_{U \rightarrow X}$  for any  $U$

**Definition 10.0.3.** Given  $\tau$ , a sieve is called a *covering sieve* if it contains some cover.

**Example 10.0.4.** If  $\mathcal{C}$  is the category of opens of a topological space  $X$  then a sieve on  $X$  is a collection of open in  $X$  stable under subsets.

**Theorem 10.0.5.** A presheaf  $\mathcal{F}$  satisfies,

$$\mathcal{F} \text{ is a sheaf} \iff \text{Hom}(S, \mathcal{F}) = \text{Hom}(h_X, \mathcal{F}) \text{ for all covering sieves } S \subset h_X$$

*Remark.* This shows that the category of sheaves recovers the covering sieves because we can take the sieves to be those that satisfy,

$$\text{Hom}(S, \mathcal{F}) = \text{Hom}(h_X, \mathcal{F})$$

for all sheaves  $\mathcal{F}$ .

### 10.1 Example

We want to show that  $\mathcal{M}_g^a$  is an algebraic space. First we need to show it is a sheaf in the étale (or smooth) topology. In fact, this will work in the fpqc topology.

**Theorem 10.1.1.** The data of  $(X, \mathcal{L})$  where  $\mathcal{L}$  is ample descends because we can descend the algebra,

$$\bigoplus_{n \geq 0} \mathcal{L}^{\otimes n}$$

which determines  $X$  via embedding into projective space.

## 11 April 27

Suppose  $G \curvearrowright X$  where  $G$  is a geometric group. We want to define  $X/G$  as an algebraic space.

**Example 11.0.1.** We want,

- (a)  $X \rightarrow Y$  is a  $G$ -bundle then  $X/G = Y$
- (b)  $\mathbb{Z}/2 \curvearrowright \mathbb{A}^1$  via  $x \mapsto -x$  is not a  $G$ -bundle and we want  $\mathbb{A}^1/(\mathbb{Z}/2)$  to be the GIT quotient.

What is the definition of  $X/G$  as an algebraic space? There should be a  $G$ -invariant map  $X \rightarrow X/G$  such that any  $G$ -invariant map  $X \rightarrow Y$  factors uniquely through  $X \rightarrow X/G \rightarrow Y$ ,

$$\begin{array}{ccc} X & \longrightarrow & X/G \\ & \searrow & \downarrow \text{dashed} \\ & & Y \end{array}$$

We call this the categorical quotient. There are some problems with this definition,

- (a) it might not exist
- (b)  $X \rightarrow X/G$  might not be a  $G$ -bundle e.g.  $\mathbb{A}^1 \rightarrow \mathbb{A}^1$  via  $x \mapsto x^2$  is the quotient  $\mathbb{A}^1/(\mathbb{Z}/2)$  but this is not a  $\mathbb{Z}/2$ -bundle (ramified over the origin).

Some possible answers,

- (a) define  $X/G$  as the categorical quotient
- (b) define  $X/G$  as the categorical quotient by only when  $X \rightarrow X/G$  is a  $G$ -bundle
- (c) defined it as the presheaf (or the sheafification)

$$Y \mapsto X(Y)/G(Y)$$

- (d) define it as the presheaf sending  $Y$  to equivariant maps,

$$\begin{array}{ccc} P & \longrightarrow & X \\ \downarrow & & \\ Y & & \end{array}$$

where  $P \rightarrow Y$  is a principal  $G$ -bundle. We would have to take this up to isomorphism and this will be bad if there are nontrivial automorphisms of the map  $P \rightarrow X$ .

- (e) Consider the presheaf  $h^X/h^G$  and take the sheafification to get  $X/G$ . If  $G \curvearrowright X$  freely then  $h^X/h^G$  is a separated presheaf.

**Example 11.0.2.** If  $Y = *$  and  $P$  is the trivial  $\mathbb{Z}/2$ -bundle over  $Y$  then the two maps  $P \rightarrow \mathbb{A}^1$  whose image is  $\pm 1$  have no automorphisms but the map  $P \rightarrow \mathbb{A}^1$  whose image is 0 does have an automorphism because the action is not free.

**Definition 11.0.3.** The action  $G \curvearrowright X$  is free if it is free on  $T$ -points  $G(T) \curvearrowright X(T)$ .

**Example 11.0.4.** An elliptic curve is  $E = \mathbb{C}/\Lambda$  analytically and indeed  $h^E = (h^{\mathbb{C}}/h^{\Lambda})^{++}$ . Algebraically we have  $\Lambda \curvearrowright \text{Spec}(\mathbb{C}[t]) = \mathbb{A}_{\mathbb{C}}^1$  where  $\Lambda$  is a discrete group viewed as a scheme. And we can define  $\mathbb{A}_{\mathbb{C}}^1/\Lambda$  which is an algebraic space but not isomorphic to an elliptic curve! However  $(\mathbb{A}_{\mathbb{C}}^1/\Lambda)^{\text{an}} \cong \mathbb{C}/\Lambda$  so  $(\mathbb{A}_{\mathbb{C}}^1/\Lambda)^{\text{an}} \cong E^{\text{an}}$  but the isomorphism (the Weierstrass  $\wp$ -function) is not algebraic.

## 12 May 6

Question: how many times do you need to plus  $h^U/h^R$  to get a stack?

### 12.1 How do we tell if a stack is DM

**Proposition 12.1.1.** If  $\mathcal{M}$  is DM then  $\mathcal{I}_{\mathcal{M}} \rightarrow \mathcal{M}$  is unramified.

*Proof.* Consider,

$$\begin{array}{ccc} R & \longrightarrow & U \times U \\ \downarrow & & \downarrow \\ \mathcal{M} & \longrightarrow & \mathcal{M} \times \mathcal{M} \end{array}$$

where the downward maps are étale. However,  $R \rightarrow U$  is étale and hence unramified so  $R \rightarrow U \times U$  is unramified.  $\square$

**Proposition 12.1.2.** If  $\mathcal{M}$  is an algebraic stack and  $\mathcal{I}_{\mathcal{M}} \rightarrow \mathcal{M}$  is unramified then  $\mathcal{M}$  is DM.

*Proof.* Given a smooth cover  $U \rightarrow \mathcal{M}$ . For each point  $p \in U$  where the relative dimension  $n > 0$  we want to slice to find an étale neighborhood.  $\square$

## 13 May. 9

Let  $\mathcal{M}$  be an algebraic stack (meaning a locally representable stack in the smooth topology on schemes).

**Definition 13.0.1.** The inertia stack,

$$\begin{array}{ccc} \mathcal{I}_{\mathcal{M}} & \longrightarrow & \mathcal{M} \\ \downarrow \Delta & & \downarrow \Delta \\ \mathcal{M} & \xrightarrow{\Delta} & \mathcal{M} \times \mathcal{M} \end{array}$$

is defined by the above fiber product.

**Proposition 13.0.2.** Let  $\mathcal{M}$  be an algebraic stack, then  $\mathcal{M}$  is as an algebraic space if and only if  $\mathcal{I}_{\mathcal{M}} \rightarrow \mathcal{M}$  is an isomorphism.

**Proposition 13.0.3.** The following are equivalent,

- (a)  $\mathcal{M}$  is DM
- (b)  $\Delta$  is unramified
- (c)  $\Omega_{\mathcal{M}/\mathcal{M} \times \mathcal{M}} = 0$
- (d)  $\Omega_{\mathcal{I}_{\mathcal{M}}/\mathcal{M}} = 0$ .

**Theorem 13.0.4.** Let  $\pi : X \rightarrow Y$  be proper flat, whose geometric fibers are reduced and connected with  $Y$  locally noetherian. Let  $\mathcal{L}$  be a line bundle on  $\mathcal{L}$ . Then the presheaf sending  $Z \rightarrow Y$  to data  $(\mathcal{M}_Z, \varphi)$  where  $\varphi : \pi_Z^* \mathcal{M}_Z \xrightarrow{\sim} \mathcal{L}|_Z$  is an isomorphism of line bundles on  $X_Z$  for the diagram,

$$\begin{array}{ccc}
X_Z & \longrightarrow & X \\
\downarrow \pi_Z & & \downarrow \pi \\
Z & \longrightarrow & Y
\end{array}$$

This is represented by a locally closed subscheme of  $Y$ . If the fibers of  $\pi$  are integral then a closed subscheme.

*Remark.* If we assume  $\pi$  is finitely presented then we can drop noetherian assumptions because it is the pullback of a noetherian case and therefore the theorem holds (showing it can be pulled back from a *flat* noetherian case is the tricky part).

*Remark.* The above theorem works for a schematic morphism  $f : \mathcal{X} \rightarrow \mathcal{Y}$  of algebraic stacks because it holds after all base changes to schemes.

**Proposition 13.0.5.** For  $g \geq 2$  the stack  $\mathcal{M}_g$  sending  $B$  to families of smooth genus  $g$  curves (flat schematic smooth map of relative dimension 1 with integral curves of genus  $g$  fibers) is algebraic. It is a stack in the fpqcK topology.

*Proof.* Any family of curves  $\mathcal{C} \rightarrow B$  has  $\omega_{\mathcal{C}/B}$  relatively ample and hence we get an embedding into projective space locally. Using cohomology and base change,

$$\mathcal{C} \hookrightarrow \mathbb{P}(\pi_* \omega_{\mathcal{C}/B}^{\otimes 3})$$

Therefore, consider the locus of canonically embedded curves  $H \hookrightarrow \text{Hilb}_{\mathbb{P}^n}$  and then  $H \rightarrow \mathcal{M}_g$  is a  $\text{PGL}_n$ -torsor.  $\square$

**Proposition 13.0.6.** The stack of dimension  $n$  smooth projective varieties  $X$  where  $\det \Omega_X = \omega_X$  is ample is an algebraic stack for the fpqcK topology.

*Proof.* Let  $X \rightarrow B$  be such a family. Then there is some  $\omega_{X_0}^{\otimes N}$  which is very ample with vanishing higher cohomology. Then we consider the open substack of  $\mathcal{M}$  where  $h^{>0}(X, \omega_X^{\otimes N}) = 0$  and  $h^0$  is constant which is open by semicontinuity. Then the very ample locus is open (for flat maps the closed embedding locus is open). Then we get  $\mathcal{M}_{X_0} \subset \mathcal{M}$  open and  $H \rightarrow \mathcal{M}_{x_0}$  is a  $\text{PGL}_n$ -torsor.  $\square$

## 14 May 11

**Proposition 14.0.1.** Suppose that  $\mathcal{M}$  is an algebraic stack. Then the following are equivalent,

- (a)  $\Omega_{\mathcal{J}/\mathcal{M}} = 0$
- (b)  $\Omega_{\Delta} = 0$
- (c)  $\mathcal{M}$  has a representable étale cover by a scheme so is DM.

*Proof.* By pullback (b) implies (a) and  $\mathcal{J} \rightarrow \mathcal{M}$  has a section so (a) implies (b) by pullback as well. We showed previously that if  $\mathcal{M}$  is DM then  $\Omega_{\Delta} = 0$  since  $\Delta$  admits an étale cover by an unramified morphism. Therefore, we just need to show that if  $\Omega_{\Delta}$  then  $\mathcal{M}$  is DM.

Start with a smooth cover  $U \rightarrow \mathcal{M}$  by a scheme  $U$ . We need to slice  $U$  to make it étale. We can shrink and take disjoint union so we may take  $U = \text{Spec}(A)$ . Now consider,

$$\begin{array}{ccc} R & \xrightarrow{\pi_1} & U \\ \downarrow \pi_2 & & \downarrow \\ U & \longrightarrow & \mathcal{M} \end{array}$$

To slice a smooth morphism we just need that its restriction to the fiber cuts down the dimension of the differentials by one. Consider the sequence for  $R \rightarrow U \times U \rightarrow \mathcal{M}$ ,

$$\pi_1^* \Omega_{U/\mathcal{M}} \oplus \pi_2^* \Omega_{U/\mathcal{M}} \longrightarrow \Omega_{R/\mathcal{M}} \longrightarrow \Omega_{R/(U \times U)} \longrightarrow 0$$

Since  $R \rightarrow U \times U$  is unramified we see that  $\Omega_{R/U \times U} = 0$  and thus any function  $f \in \mathfrak{m} \setminus \mathfrak{m}^2$  for a point  $\mathfrak{m} \subset A$  then it has a nonzero differential using the sequence (with structure map  $\pi_2 : R \rightarrow U$ ),

$$\pi_2^* \Omega_{U/\mathcal{M}} \longrightarrow \Omega_{R/\mathcal{M}} \longrightarrow \Omega_{R/U} \longrightarrow 0$$

So we see from these sequences that  $\pi_1^* \Omega_{U/\mathcal{M}} \twoheadrightarrow \Omega_{R/U}$  therefore for any covector in  $(\Omega_{R/U})_p$  arises locally from pullback of some form  $\Omega_{U/\mathcal{M}}$  which locally  $df$  for  $f \in \mathfrak{m}$  on  $\text{Spec}(A) \subset U$ .  $\square$

## 14.1 Stack of Algebraic Curves

If  $g \geq 2$  then  $H^0(C, \mathcal{T}_C) = 0$  and therefore there are no infinitesimal automorphisms. This proves that  $\Omega_{\mathcal{M}_g/\mathcal{M}_g} = 0$  so  $\mathcal{M}_g$  is DM. Furthermore, because the stabilizers are closed subschemes of  $\text{PGL}_n$  we see that  $\mathcal{M}_g$  has affine diagonal (in particular quasi-compact). However, it is unramified so we see that every genus  $g$  curve has finitely many automorphisms.

Consider genus  $g$  curves with distinct smooth marked points  $p_1, \dots, p_n \in C$  such that,

$$\mathcal{O}_C(p_1 + \dots + p_n)$$

is very ample with  $h^1 = 0$ . We claim this is an Artin stack by exactly the same argument: embed into  $\mathbb{P}^n$  in families.

## 15 May 13

*Remark.* Amazing theorem is that we don't need smooth covers, flat is enough.

**Theorem 15.0.1** (04S6). Let  $F$  be an fppf sheaf and  $f : U \rightarrow F$  a representable (by algebraic spaces) morphism which is surjective flat and locally finitely presented. Then  $F$  is an algebraic space.

**Theorem 15.0.2** (06DC). Let  $f : \mathcal{X} \rightarrow \mathcal{Y}$  be a morphism of stacks in the fppf topology. Suppose that  $\mathcal{X}$  is an algebraic stack,  $f$  is representable by algebraic stacks which is surjective locally of finite presentation and flat. Then  $\mathcal{Y}$  is an algebraic space.

Return to  $\mathcal{M}_{g,n}^{vp}$  is the moduli stack of families  $f : \mathcal{C} \rightarrow B$  with  $f$  flat finitely presented with  $n$  sections whose geometric fibers are 1-dimensional schemes where the sections are distinct smooth points  $p_1, \dots, p_n \in \mathcal{C}_{\bar{s}}$  and  $\mathcal{C}_{\bar{s}}$  has arithmetic genus  $g = 1 - \chi(C, \mathcal{O}_C)$  and,

$$\mathcal{O}(p_1 + \dots + p_n)$$

is very ample with vanishing  $h^1$ .

*Remark.* The genus can be weird for example  $g(\mathbb{P}^1 \sqcup \mathbb{P}^1) = -1$ . But this really is the right notion because  $\chi$  is locally constant in flat families.

**Proposition 15.0.3.** Why is  $B \hookrightarrow \mathcal{C}$  via the sections  $\sigma_i$  effective Cartier divisors. We need to show  $\mathcal{I}_{B/\mathcal{C}}$  is invertible. There is a sequence,

$$0 \longrightarrow \mathcal{I}_{B/\mathcal{C}} \longrightarrow \mathcal{O}_{\mathcal{C}} \longrightarrow \mathcal{O}_B \longrightarrow 0$$
