

# 1 Introduction

The  $\lambda$ -calculus (here we first introduce pure untyped  $\lambda$ -calculus) is a formal system designed to capture of the notions of “function” and “composition”.

*Remark.* A  $\lambda$ -expression will be a finite string made from the symbols  $\lambda$ ,  $.$ , and an infinite list of variable symbols  $x, y, z, \dots$  or  $a, b, c, \dots$  or  $x_1, x_2, x_3, \dots$  whatever you want to call them. We think of  $\lambda x.M$  as the function that takes in  $x$  and returns  $M$  where  $M$  is an expression possibly involving  $x$ .

**Definition 1.0.1.** A *well-formed*  $\lambda$ -expression is defined recursively via,

- (a) any variable is a  $\lambda$ -expression
- (b) if  $M$  is a  $\lambda$ -expression then  $\lambda x.M$  is a  $\lambda$ -expression
- (c) if  $M$  and  $N$  are  $\lambda$ -expressions then  $(MN)$  is a  $\lambda$ -expression.

*Remark.* We have already said that we should interpret  $\lambda x.M$  as a function. Then  $(M, N)$  is an “application” of the function  $M$  to  $N$ . We think of  $((\lambda x.M)N)$  “evaluating” to  $M[x := N]$  which is how this system captures the essence of functions and computation as evaluation though substitution. Although intuitively we think of  $\lambda$ -expressions as functions, that actually take an input and produce a well-defined output, this is actually difficult to define because we will have to decide when a computation is “finished” and in fact computations may not halt complicating our desire to call these things functions. A major goal will be to somehow interpret these objects as honest-to-god functions. For now, we take a different perspective not that  $\lambda$ -expressions are “machines” but rather they are formal strings in a formal system. To create a formal system we need “rules of inference” which are conventionally called conversions and reductions.

**Definition 1.0.2.** REDUCTIONS AND COVERESIONS

EXAMPLES

NORMAL EXPRESSIONS

CHURCH-ROSSER

UNIQUENESS OF NORMAL FORM

**Example 1.0.3.** A  $\lambda$ -expression need not admit a normal form. For example let,

$$\omega = \lambda x.(xx)$$

this is the function that applies its input to itself. What happens if we apply  $\omega$  to itself then we get,

$$\Omega = (\omega\omega)$$

and it is easy to see that,

$$\Omega \triangleright_{\beta,1} \Omega$$

and there are no other possible  $\beta$ -reductions. Therefore  $\Omega$  does not have a  $\beta$ -normal form. We can think of it as corresponding to a computation that does not halt.

## 2 Arithmetic and Logic in the $\lambda$ -Calculus

CHURCH ENCODING AND SIMPLE FUNCTIONS

### 3 “Consistency” of the $\lambda$ -Calculus

EARLY FORM INCONSISTENT

Look at section here <https://plato.stanford.edu/entries/lambda-calculus/>  
and in Barendregt’s book.

THIS FORM IS CONSISTENT IN THE SENSE OF CANNOT DERIVE EVERYTHING  
CURLY’S PARADOX
